A.1. Data

A.1.1. DOI briefings

Parsing and Gemini Code — A large number of DOI news briefings have been posted on documentcloud.org, which is a website where newsrooms and independent journalists post documents, especially documents produced following FOIA requests. In order to post documents publicly, an account must be verified as belonging to a journalist or other approved organization. Using documentcloud.org, I found daily news reports from the Department of Interior (DOI) from February 19, 2015 to May 30, 2019 ($n = 223$). All of the 2015-2018 DOI reports were created by Bulletin Intelligence ($n = 216$). The 2019 reports were produced by Barbaricum ($n = 7$).

I implemented a multi-stage process to convert pdf documents into structured text data suitable for analysis. The majority of documents were already machine-readable; for the remainder, I applied Optical Character Recognition (OCR) using Adobe Acrobat to extract the underlying text. I employed rule-based pattern matching to identify section headings from the table of contents and parsed each document according to these headings.

To extract named entities corresponding to media sources, I used the Gemini 2.0 Flash large language model (LLM) to perform entity recognition and classification. After splitting the DOI news briefings by page, I used the following prompt to extract the sources from each page using the Gemini LLM:

```
# Define the model
model_id =  "gemini-2.0-flash"

# Define response schema
class Citation(BaseModel):
    source: str = Field(description="Name of news source cited in text. Reproduce the exact text. Write 'unable
                                    to determine' if not certain or no news source is detected.")
    sourceinfo: str = Field(description="All text related to the the news source and any associated  text in () or [].
                                      Write 'unable to determine' if not certain or no news source is detected.")
    page: str = Field(description="Page number of pdf")
class Sources(BaseModel):
    """For each page of the pdf, extract the news sources cited in the document."""
    citations: list[Citation] = Field(description="The list of news sources")

# API Call
def extract_source_gemini(file_path: str, model: BaseModel):
    # Upload the file to the File API
    file = client.files.upload(file=file_path, onfig={'display_name': file_path.split('/')[-1].split('.')[0]})
    # Generate a structured response using the Gemini API
    prompt = f"Extract the structured data from the following PDF file"
    response = client.models.generate_content(model=model_id, contents=[prompt, file],
                                            config={'response_mime_type': 'application/json',
                                                    'response_schema': model})
    # Convert the response to the pydantic model and return it
    return response.parsed
```

To convert the DOI briefings into structured data, I used the Gemini 2.0 Flash large language model (LLM) to identify all news sources in the briefings and extract the original text for each source, including any typos. I manually reviewed the resulting list of text snippets, removed misidentified sources, and added website domains. I then split the documents by heading and searched each section for the source text snippets. Rather than search the full text, I only searched 10 word chunks preceding each forward parenthesis ("("). In the document text, news source names were almost always followed by descriptive information enclosed in parentheses.

The Gemini model output was used to generate a candidate list of text snippets corresponding to news outlets. These candidate entities were then cleaned, normalized, and matched to entries in the Abyz News Links dataset using string matching on outlet names. To address gaps and correct misclassifications, I manually validated the matched entities, removing false positives where necessary, and assigned standardized names. For sources appearing multiple times in the LLM output, I also appended corresponding URLs when available. This process resulted in a list of 1,295 standardized media names.

In the document text, news source names were almost always followed by descriptive information enclosed in parentheses. To leverage this pattern, I split the text by "(" and retained the preceding 10 words as context. I then searched each chunk for any of the text snippets that had been originally identified as sources.[1] When multiple sources were discovered, I created a new row for each source. Sometimes, this occurred when a story was co-produced by multiple news outlets, but it also occurs when there is a false-positive. In total, I identified at least one source in 31,456 of the 51,856 text chunks that I searched. I identified 1,925 cases with multiple sources. For these cases, I kept the source with more characters because the false positive tended to be shorter (e.g. sun, time, vice, ap). I included both sources in 59 cases where both sources were the same length.

Biased DOI sample? — Unlike the other agencies, the DOI sample is not complete and depends on the FOIAs submitted by journalists and non-profits. The composition of the DOI briefing sample depends on the documents uploaded to Document Cloud

[1] e.g. for abc, I searched for phrases like "abc world news", "abc's this week", "abc news", and "abc's â€œthis weekâ€".

and the FOIAs that produced them. In total, I identified sixty-six relevant Document Cloud uploads. Based on the document titles, tags, and other metadata, some of the FOIAs concerned Bears Ears and Grand Staircase-Escalante National Monuments, but other FOIAs sought information relevant to other topics like Ryan Zinke's corruption scandal in 2018. Many of the documents were uploaded by environmental nonprofits. Out of 223 briefings, 86 mention 'bears ears' at least once and 96 mention 'bears ears' or 'grand staircase.' About half of the briefings are from 2017 (122). Only about a fifth of the briefings are from 2015 to 2016 (45).

Thus, DOI briefings are more likely to be in the sample if they mention topics related to FOIAs from journalists or interest groups. While this could introduce bias, topics become more or less relevant over time. For example, FOIAs prompted by Ryan Zinke's corruption scandal would be limited to time periods where he was suspected of malfeasance. This means that the potential bias is issue-specific and time-bound, rather than systematically skewing the entire dataset. Moreover, if temporary spikes in FOIA-related topics are drive the overall results, the results would vary over time. To test for sampling bias, I verify that my results are consistent across the whole time period covered by the briefings (see Figure A27).

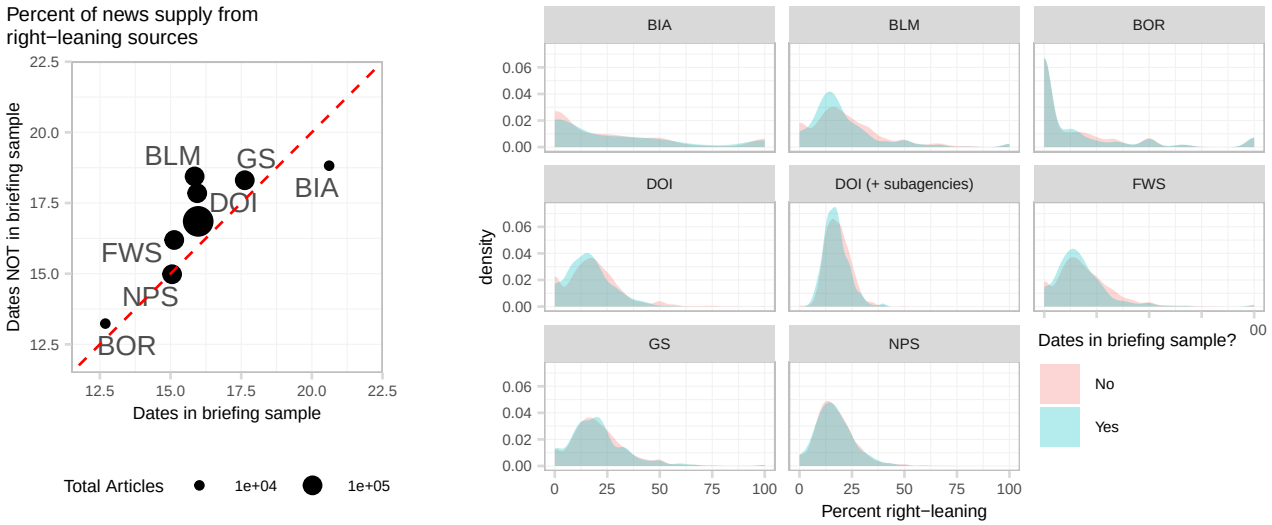

Figure A1: Comparison of DOI news supply on dates represented in the briefing sample and on other dates during the same period. Data from Media Cloud. Queries are agency names. Density plots show distribution of data aggregated to the level of publication date for the density plots.

In Figure A1, I check whether the supply of news about DOI and the DOI subagencies is different during the dates where I have briefings using the data used to construct Figure 3 in the paper. Dates in DOI briefing sample include news published on the same day as a briefing in my sample or 1 day prior to a briefing in my sample. For briefings published on Mondays, I include articles published up to 2 days before a briefing in my sample briefing. Dates not in briefings includes all other dates between February 19, 2015 to May 30, 2019.

Figure A1 shows that across all articles mentioning DOI or its subagencies (BOR, NPS, FWS, BLM, GS, BIA), the time periods covered by the DOI briefing sample contain slightly less right-leaning news, but the difference is small compared to the difference observed in Figure 1. During the briefing periods, 16.0% of the news supply is right-leaning. During the other periods, 16.9% of the news supply is right-leaning.

A.1.2. Media Bias/Fact Check (MBFC)

On June 2, 2025, I downloaded MBFC scores using the MBFC API (https://rapidapi.com/mbfcnews/api/media-bias-fact-check-ratings-api2). However, I merged the API data with additional information because MBFC combines its scores for partisan slant and factual accuracy. For sources that have been deemed factually questionable, the partisan slant score is replaced by 'Questionable' in the API database. Thus, to obtain partisan slant scores for all sources, I also scraped the MBFC website using the MBFC page URLs provided by the API. I identified several places where partisan slant data could be found on the website (a table in the text and the filename of an image).

To construct a bias variable from these three sources of information (the API, website text, and website image filename), I first created flag variables for each category. I created a variable called `right`, which was 1 if the source was categorized as 'right' by the API, webpage text, or webpage image filename. I also created a variable called `left`, which would be 1 if the source was categorized as 'left' by the API, webpage text, or webpage image filename. Lastly, I created a variable called `center`, which would be 1 if the source was categorized as 'least biased' by the API, webpage text, or webpage image filename. I created a variable called `other`, which was equal to 1 if the source was categorized as a 'satire' by by the API, webpage text, or webpage image filename. Lastly, I created a variable called `notrated`, which was 1 if the source was not categorized as right, left, center, or other (e.g. it was listed as "not rated", "na", "unrated", "pro-science", "pseudoscience", or "junk news"). `notrated` was also 1 if the source was listed as both right and left.

To construct a final partisan bias variable, I used the following rules to determine whether a source was categorized as left, right, center, other, or not categorized:

- Right-leaning: (`right`=1) and (`left`=0)
- Left-leaning: (`left`=1) and (`right`=0)
- Center: (`center`=1) and (`right`=`left`=0)
- Other: (`other`=1) and (`center`=`right`=`left`=0)
- Not Categorized: ((`notrated`=1) and (`other`=`center`=`right`=`left`=0)) OR (`right`=`left`=1)

Some webpages also provided the numeric score for partisan bias as well. However, most of them were missing the negative sign (-) if they were liberal. Thus, I recalculated the numeric scores by multiplying the number by -1 if the score was from a liberal-leaning website. These continuous scores are available for only part of the sample. They are only used in the Appendix as a robustness check and to determine source extremity.

Table A1: Agreement between MBFC and Allsides Scores

Source Type	Total Sources	Total Agree	Percent Agreement
Excluded (local)	578	336	58.1
Included	250	190	76.0

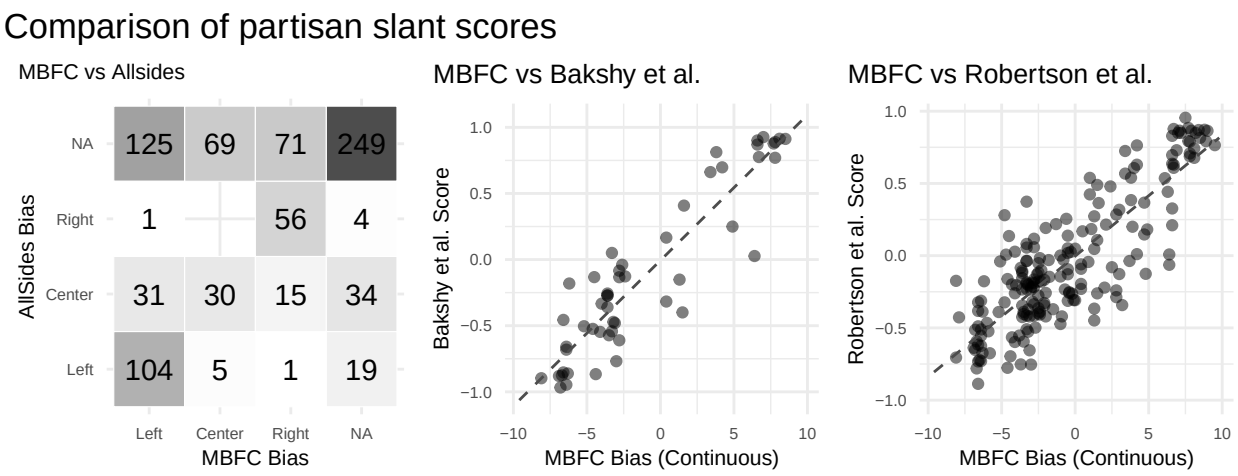

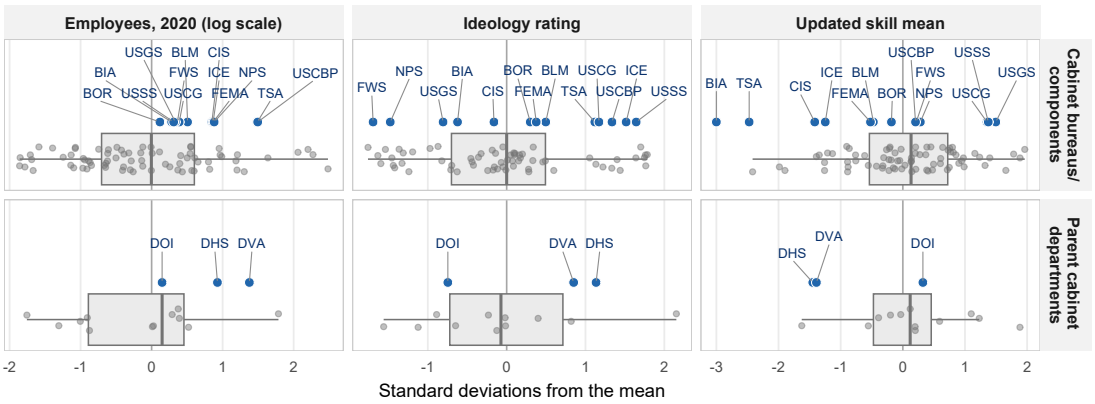

Figure A2: Comparison of media bias scores. Limited to sources cited in briefings. Excludes local general interest sources and government websites.

A.1.3. Summary Statistics

Table A2: Summary Stats for Briefings and Agencies

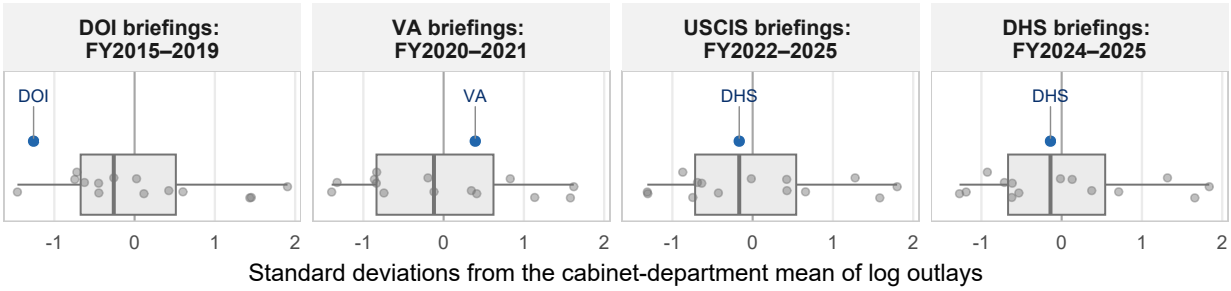

Briefing	Agency	Part of Briefing	Years	Total Articles	Total Dates	Avg Articles per Day	Unique Source Domains	Unique Source Names	Local General Interest	Gov Websites	Unidentified	International
DOI	DOI	Whole Briefing	2015-2019	39,410	223	176.7	2,235	2,451	11,437	4	0	11,800

DHS	USICE	Section	2024-2025	7,576	618	12.3	285	281	1,140	2	20	1,047
Total			2015-2025	160,275	1,573	101.9	4,158	4,504	41,187	338	176	41,224

A.1.4. Agency Representativeness

Grey points are not included in the briefing analysis; blue labeled points are included in the briefing analysis. Employment is log10-transformed before standardization.

Figure A3: Representativeness of agencies in the briefing analysis. Data from Richardson, Piper and Lewis (2025).

Each panel averages outlays over the fiscal years covered by one briefing series. Blue point: the department whose briefings define the panel (DHS for USCIS, which has no separate line in Table 4.1). Grey points: the other cabinet departments. Source: OMB Historical Table 4.1. Window-average outlays are log10-transformed, then standardized using the mean and SD of all 15 cabinet departments in that window.

Figure A4: Comparing budget data of cabinet agencies in the briefing analysis to other cabinet agencies. Average of years in each briefing dataset. Budget data from OMB Historical Tables, Table 4.1-Outlays by Agency: 1962–2031.

Table A3: Representation of agencies in the briefing analysis by organizational type. Data from Richardson, Piper and Lewis (2025).

Organization type	Eligible units	Included units	Included (%)
Cabinet department	15	3	20.0
Cabinet bureau/component	103	13	12.6
Independent commission	18	0	0.0
Independent commission component	3	0	0.0
Other independent agency	15	0	0.0
EOP unit	8	0	0.0
Other bureau/component	1	0	0.0

A.2. Figure 1 - Association between sources in briefings and partisan slant

Table A4 contains the regression coefficients for the best fit line in the right-leaning subplot of Figure 1. The table also shows that these results are consistent across different specifications. Figure A5 replicates Figure 1 using different media slant measures and shows the relationship between missing slant and agency ideology.[2] Figure A6 replicates Figure 1 using an alternate agency ideology measure from Napolio (2025), which ranges from -10 to 10.

[2]Note: the Bakshy et al. scores were downloaded from the replication materials for Guess (2021).

Table A4: Best fit line in Right-leaning subplot of Figure 1

	MBFC	MBFC, keep NA	MBFC, disaggre-gated	MBFC, continuous	MBFC, keep local+gov	MBFC, drop specialized	Alt ideo measure
(Intercept)	0.202***	0.186***	0.267**	0.462***	0.201***	0.194***	0.168***
	(0.024)	(0.023)	(0.075)	(0.010)	(0.018)	(0.025)	(0.017)
'Agency Ideology'	0.062**	0.059**	0.053***	0.024**	0.048**	0.067**	
	(0.018)	(0.017)	(0.012)	(0.008)	(0.016)	(0.017)	
'Agency Ideology (Napolio)'							0.019***
							(0.002)
Num.Obs.	17	17	137 432	17	17	17	17
R2	0.305	0.295	0.009	0.286	0.277	0.326	0.711
R2 Adj.	0.259	0.248	0.009	0.239	0.229	0.281	0.692

Notes: Standard errors in Cols 1-2, 4-7 are heteroskedasticity-robust.
Cols 1-2, 5-6: Dependent variable (DV) is proportion of articles in an agency's briefing from right-leaning sources, ranges from 0 to 1.
Col 3: DV is 1 if an article is from a right-leaning sources and 0 otherwise. Errors clustered by the agency, news sources, and article.
Col 4: DV is the average value of the MBFC continuous variable, rescaled from 0-1.
Col 7: DV is same as col 1, Ricardson et al agency ideology scores replaced with scores from Napolio (2025), ranges from -10 to 10.

Figure 1 replicates with other partisan slant measures

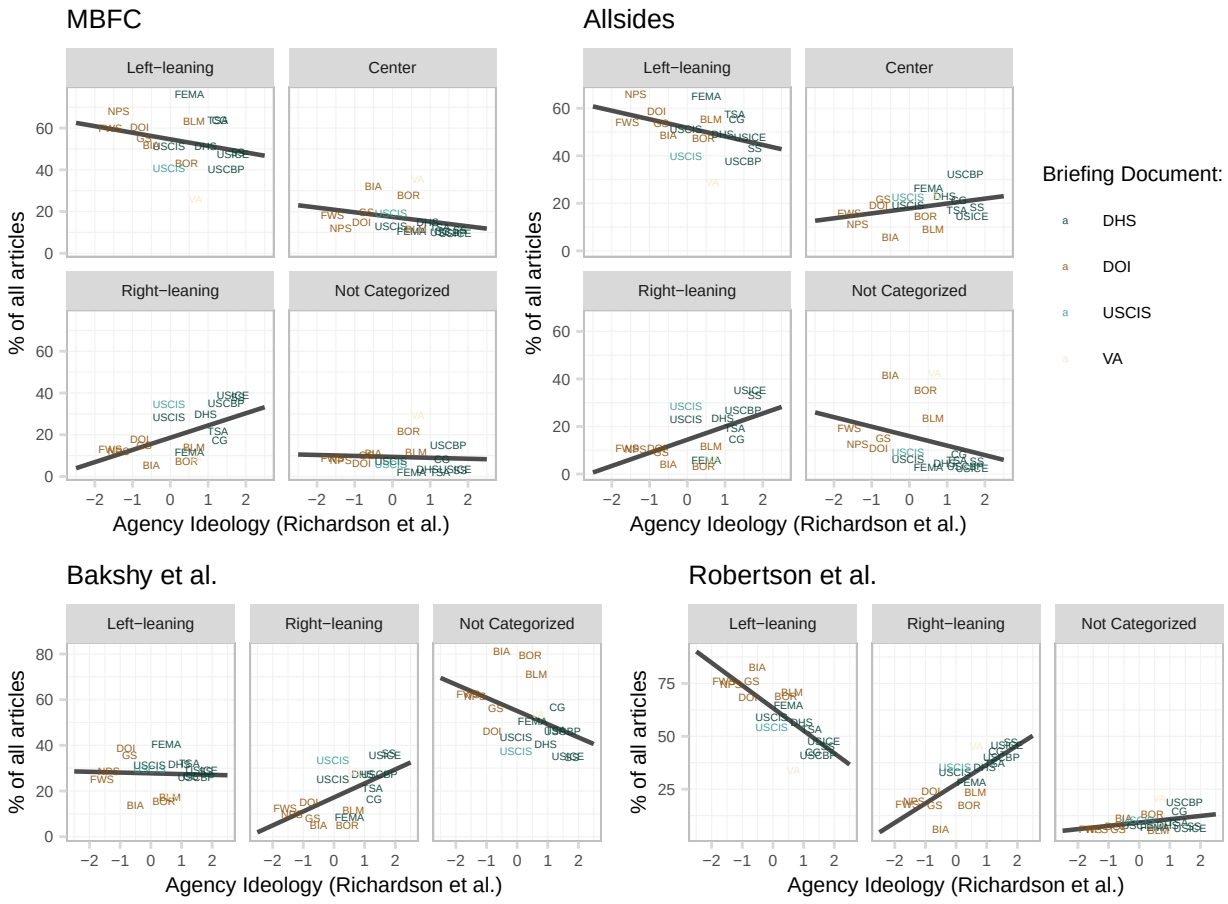

Figure A5: Replication of Figure 1 with alternate partisan slant scores.

Figure 1 replicates with other agency ideology measure

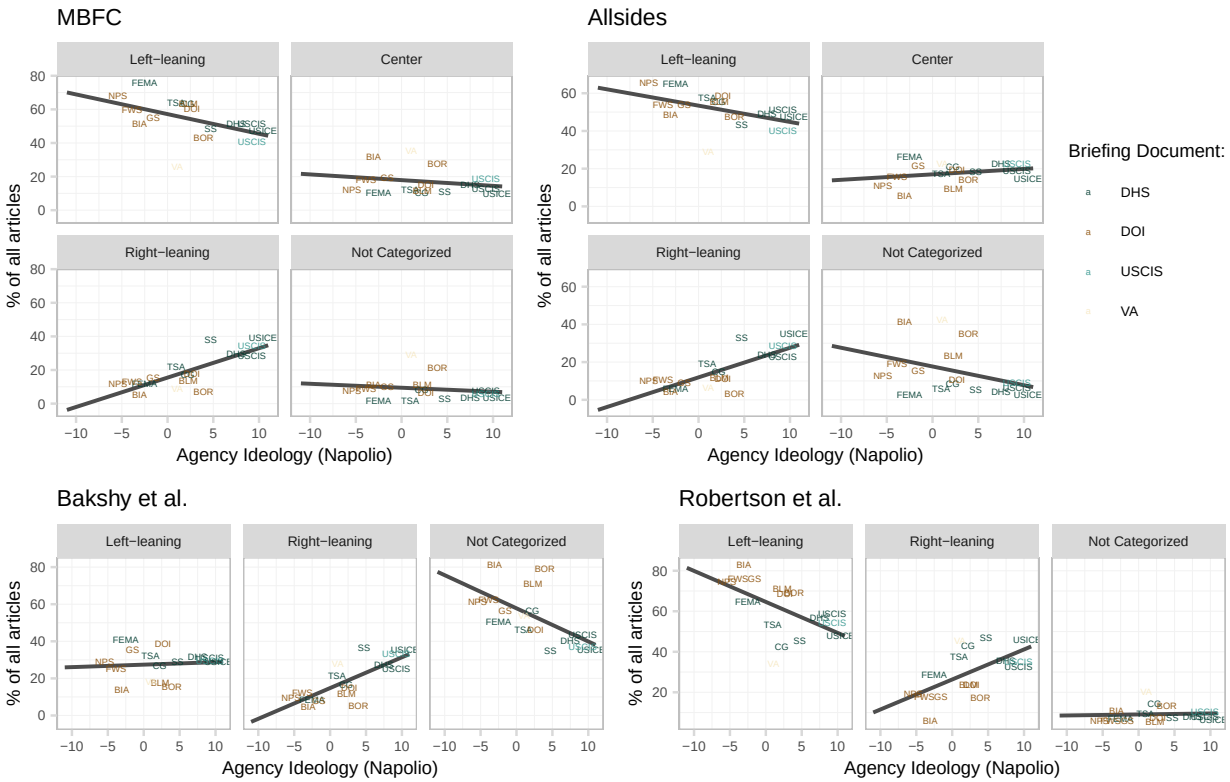

Figure A6: Replication of Figure 1 with Napolio (2025) agency ideology measures.

A.3. Figure 3 - Association between news supply and partisan slant (briefing agencies and time periods)

Dates included in Supply of News—When I have a complete sample of briefings, I collect all news published between the first and last briefing in the sample. For the DOI and its subagencies, I subset the Media Cloud results to articles in the window directly before the date of a briefing in the sample. The results replicate when the window size varies.

Because I do not have the complete set of daily news briefings for the Department of Interior, I had to make an assumption about which articles from Media Cloud should be considered part of the supply for Figure 3.[3] In Figure A7, I show that most articles were included in the briefing 1 day after being published. However, there is some variation. Breaking down the distribution by the day of the week that the briefing was published (Monday, Tuesday, etc), we see that Monday briefings include slightly older articles. I did not find any Sunday DOI briefings, suggesting that DOI briefings are not produced on Sundays. Likely, Monday briefings contain coverage from Saturday and Sunday. Thus, when I determined the relevant supply of news for the DOI briefings in my sample, I included an extra day for briefings published on Mondays. The results reported in Figures 3 assume that an article is part of the DOI's relevant supply of news if it is published on the same day as a briefing in my sample or 1 day prior to a briefing in my sample. For briefings published on Mondays, I include articles published up to 2 days before a briefing in my sample briefing. As a robustness check, I also verify that the results replicate when I expanding or contracting the DOI date window affects the results. For the matched analysis in Figure 4, I drop the day of the briefing because the matched analysis is more sensitive to misspecifying the true supply of news. Adding back the day of the briefing does not change the results (see Appendix A.7).

Robustness of Figure 3—The other figures below test the robustness of the findings in Figure 3. Figure A8 compares the slope of the best fit line in Figure 3 to the comparable best fit line of Figure 1 (after removing sources not found in Media Cloud). Across different specifications, the supply-side disparity is similar sized or larger than the disparity in the briefings. In Figure A8, agency ideology measures are standardized to range from 0 to 1, with higher values indicating more conservative agencies.

[3]Note that I have not replicated Figure 3 or 4 using the GDELT data. This is because the GDELT API does not report article publication date.

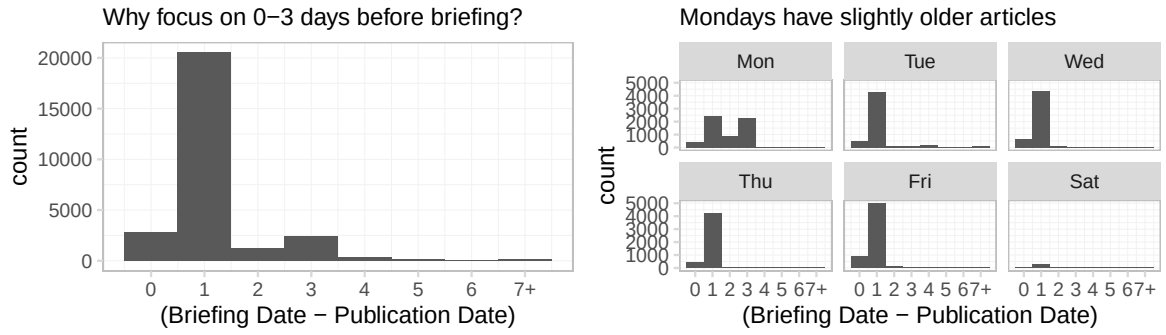

Figure A7: Days between DOI briefing and article publication. Based on article publication date metadata provided in DOI briefing. Excludes local general interest sources and government websites. Plot (ii) shows the distribution grouped by the day of the week of the briefing. No DOI briefings were found for Sundays, suggesting that they are only produced 6 days a week.

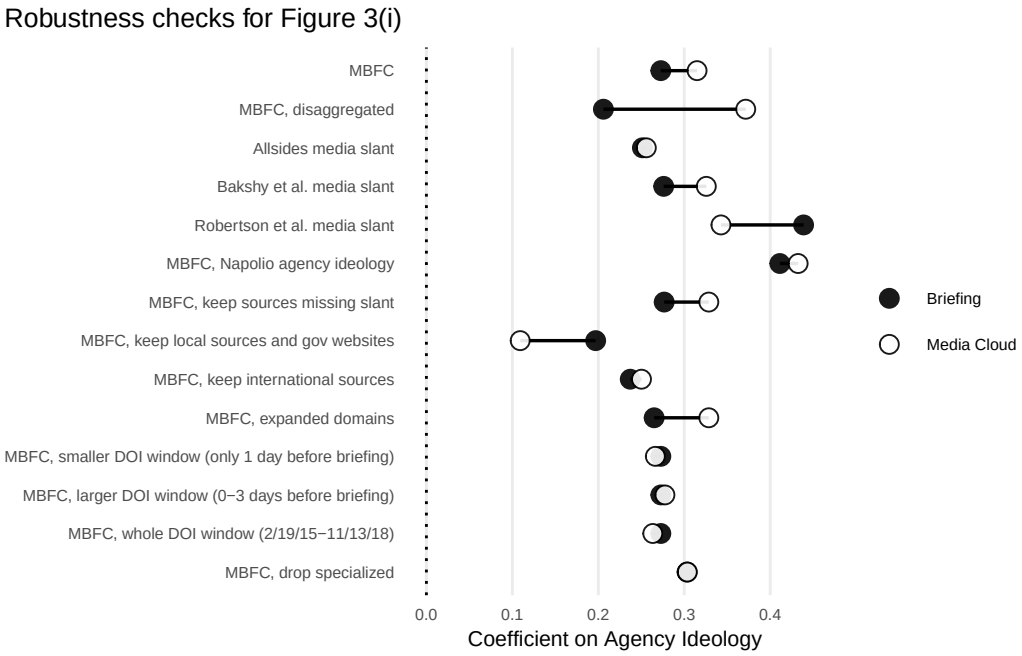

Figure A8: Robustness of finding in Figure 3. Open dots are estimates from regressions using Media cloud data. Closed dots are esimates from regressions using briefing data, after dropping articles from sources that do not appear in the Media Cloud sample. Agency ideology measures are standardized to range from 0 to 1, with higher values indicating more conservative agencies.

A.4. Figure 5 - Association between news supply and partisan slant (all agencies, 2015-2025)

A.4.1. Figure 5 robustness checks

Figure A9 reproduces Figure 5 for each facet in Figure 1 and treats missing slant as a fourth slant category. Figure A10 replicates Figure 5 with different samples (e.g. results when local news is included). The GDELT results are based on 17 randomly sampled weeks (2017-2025) from a second publicly available media database, GDELT (Global Database of Events, Language, and Tone). Figures A11 and A12 replicate Figure 5 using other media slant and agency ideology measures.

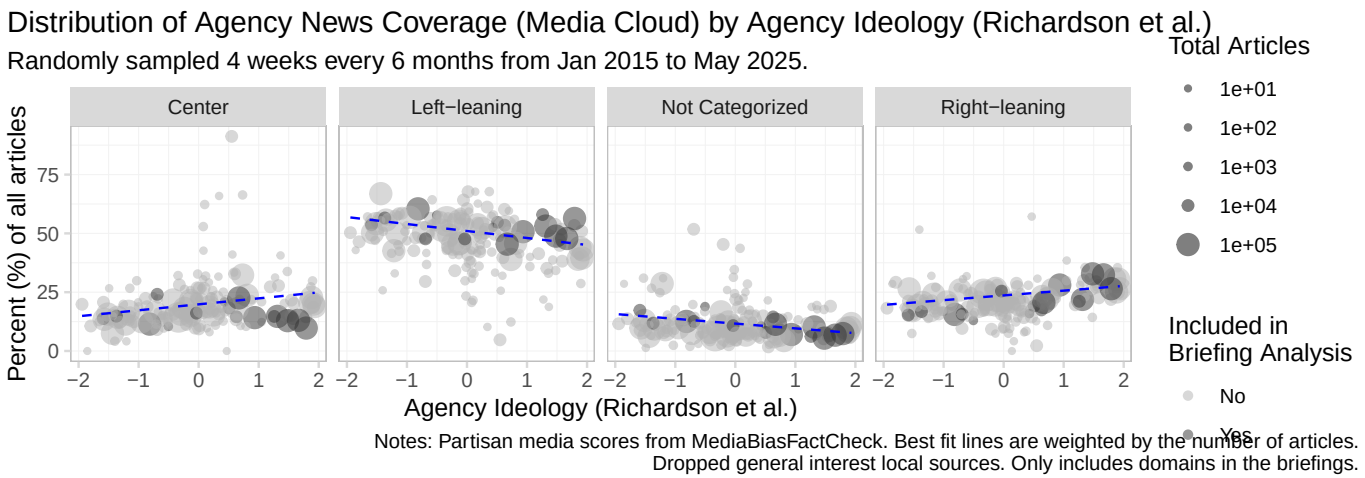

Figure A9: Replication of Fig 5 with all media slant categories. Domains without partisan slant values are included in the Not Categorized category.

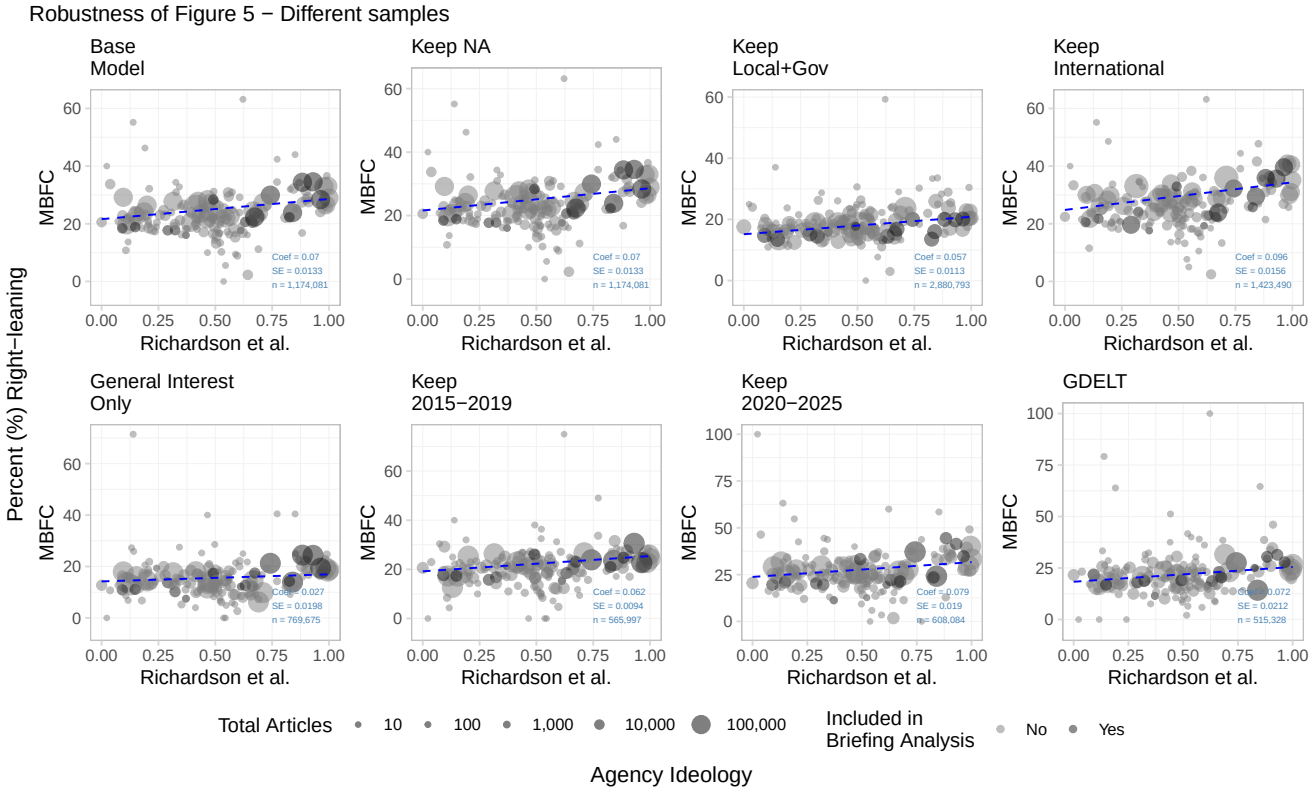

Figure A10: Replication of Fig 5 with alternate data subsets and sources. Fig 5 results after keeping articles with missing media slant, keeping local general interest news and government websites, keeping international sources, and substituting GDELT data.

Figure 5 using alternative bias and ideology measures, Media Cloud (2015−2025)

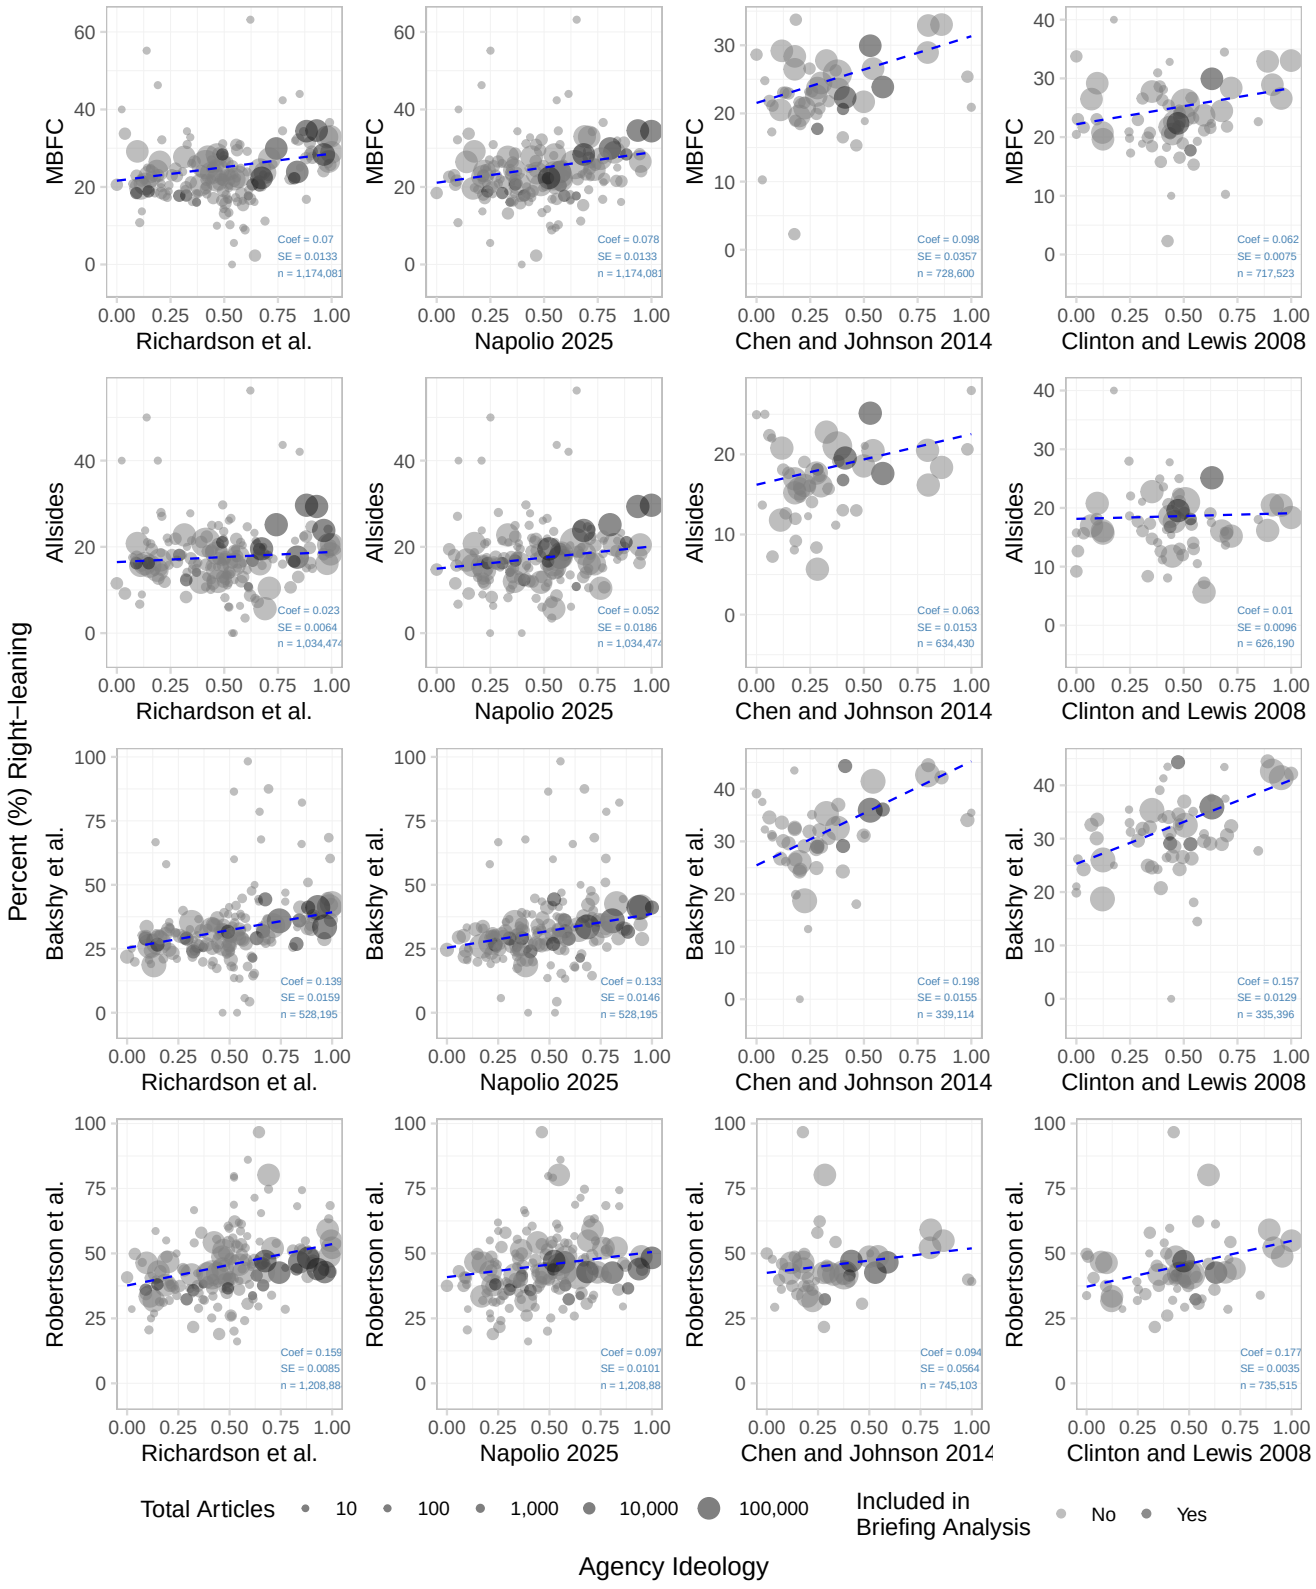

Figure A11: Replication of Fig 5 using alternative measures of news slant and agency ideology.

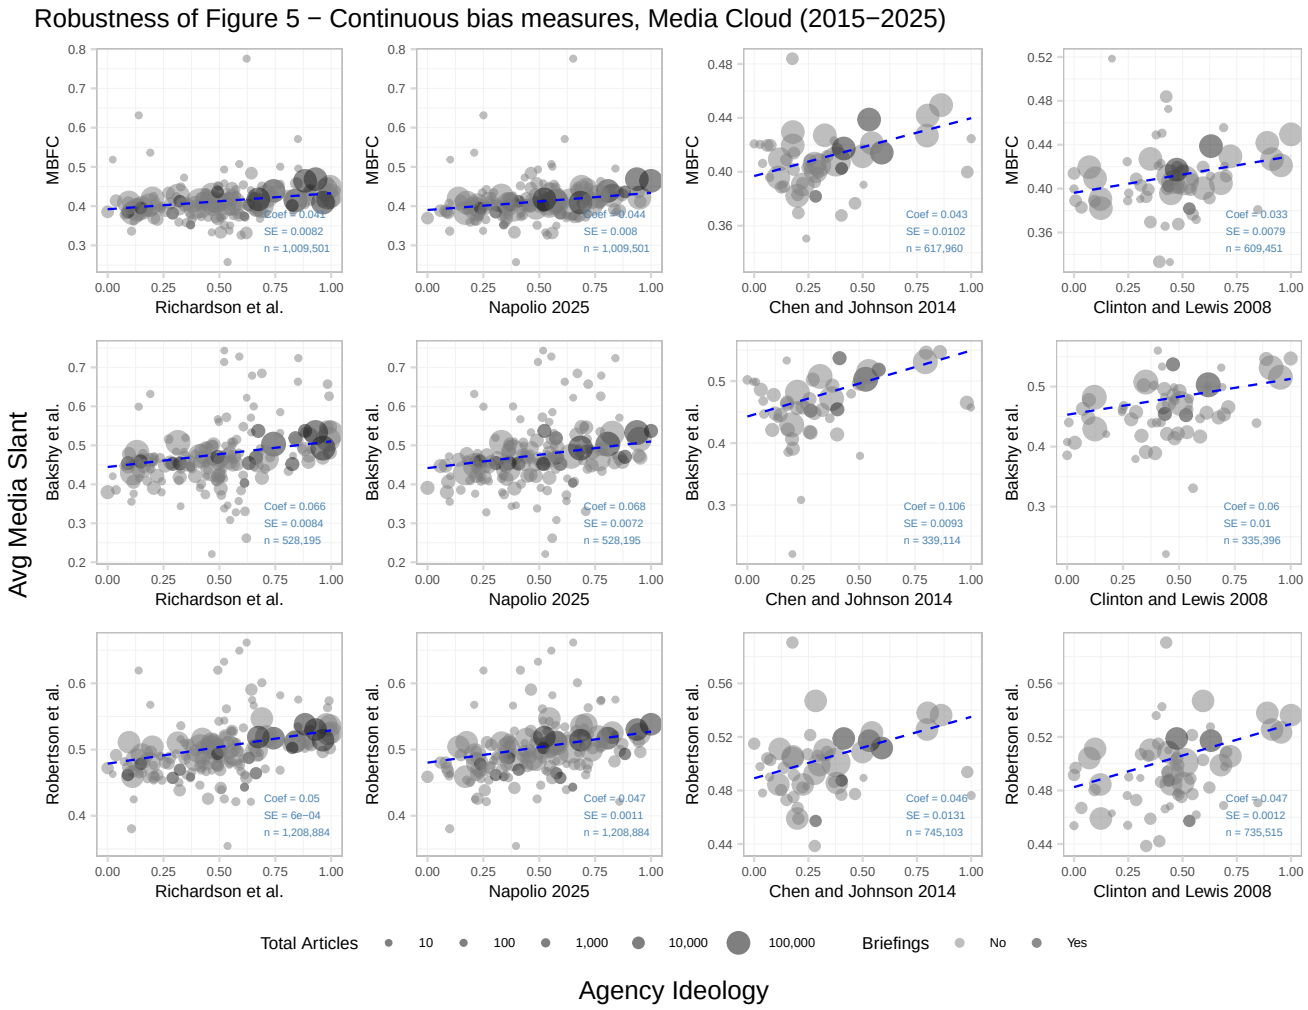

Figure A12: Replication of Fig 5 using continuous measures of slant from MBFC and Bakshy et al. (2015). Slant rescaled to between 0 and 1.

A.4.2. Extension of Figure 5 Analysis - Outlet-level heterogeneous effects

While Figure 3 in the main paper suggests that publication decisions explain why conservative and liberal agencies receive different amount of coverage, the pattern could be the result of several large news outlets. Because Media Cloud does not contain all news outlets in the briefings, a supply-side explanation is more plausible if individual-level right- and left-leaning news outlets generally display asymmetric coverage of agencies.

The y-intercept and slope of the best fit line in Figure 5 depend on the ratio of conservative vs non-conservative news sources in the Media Cloud sample, the maximum output of each source, and how each source decides to allocate its resources to different stories. Because the ratio and output are fixed for each time period, any differences in the amount of coverage a news outlet gives to a particular agency will be the product of publication/editorial decisions.

To test for heterogeneous effects, I first run a mixed-effects model, allowing the slope and intercept of the regression to vary for each source (see Table A5). To run this model, I first aggregate the data to the source-agency level and add the total number of articles from the source in Media Cloud over the sampled time period. For every source, I calculate the proportion of coverage that it dedicates to each agency (pct_{ij}). This proportion, scaled from 0 to 100, is the outcome variable. To account for the possibility that different media outlets respond differently to agency ideology, I include random intercepts and random slopes for agency ideology by news outlet, allowing both the baseline level of coverage and the ideological effect to vary by outlet. This specification captures outlet-specific deviations from the average relationship and models heterogeneity in how outlets mention different agencies. Formally, the model can be written as $pct_{ij} = \beta_0 + \beta_1 I_{ij} + \mu_{0j} + \mu_{1j} I_{ij} + \epsilon_{ij}$ where I_{ij} is the ideology of agency, i, which varies within media outlet, j. Rather than include interactions between agency ideology and media slant, I split the sample and run separate models for each media slant category (see Table A5).

Table A5: Random effects model

	DV: Percent			
	Right	Center	Left	Not Categorized
(Intercept)	0.182***	0.256***	0.190***	0.213***
	(0.015)	(0.029)	(0.017)	(0.015)
Agency Ideology	0.054***	0.096**	-0.017+	-0.013
	(0.014)	(0.033)	(0.010)	(0.012)
SD (Intercept Source)	0.127	0.225	0.210	0.210
SD (‘Agency Ideology‘ Source)	0.117	0.263	0.111	0.152
Cor (Intercept~‘Agency Ideology‘ Source)	0.639	0.676	-0.032	0.113
SD (Observations)	0.864	1.210	0.984	1.369
Num.Obs.	14850	11715	29040	42405
R2 Marg.	0.003	0.005	0.000	0.000
R2 Cond.	0.040	0.077	0.054	0.034
RMSE	0.86	1.20	0.98	1.36

+ $p < 0.1$, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Notes: Data are aggregated to the source-agency level. The dependent variable is the percentage of all articles published by a source that mention an agency (out of 100).
Models are run separately for sources belonging to each Media Bias Fact Check (MBFC) category.
The models use lmer() from the lme4 package and allow random intercepts and random agency-ideology slopes for each source.

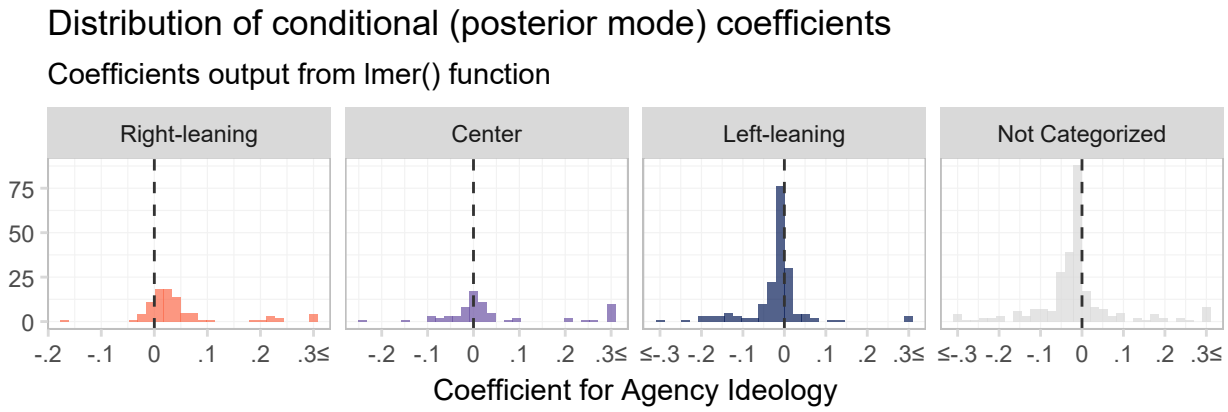

Figure A13: Effect of agency ideology on the proportion of news dedicated to liberal vs conservative agencies. Coefficients from calculated seperately for each news source. Resulting coefficients grouped by the slant of the media outlet (MBFC). Outcome is the percent of news (0-100) that an agency recieves from a news source as a percent of all articles from the source in Media Cloud. Uses same data as Figure 5, aggregated to the source-agency level.

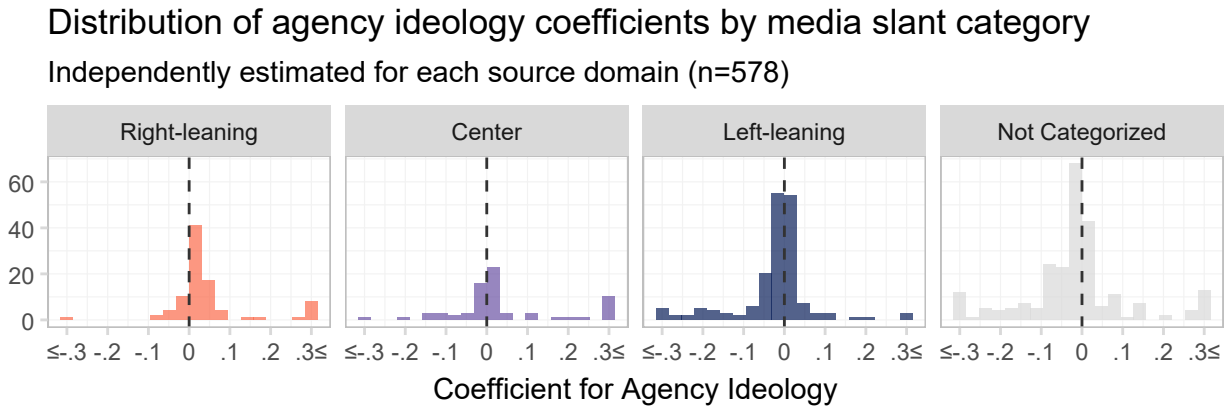

Figure A14: Effect of agency ideology on the proportion of news dedicated to liberal vs conservative agencies. To get coefficients, ran seperate regression for each news source. Source dropped if regression could not be computed (e.g. 1 data point). Resulting coefficients grouped by the slant of the media outlet (MBFC). Outcome is the percent of news (0-100) that an agency recieves from a news source as a percent of all articles from the source in Media Cloud. Uses same data as Figure 5, aggregated to the source-agency level. Tructated values above 0.3 or below -0.3.

To ensure that these results were not driven by a small number of high-frequency outlets, I also estimated separate linear

regressions of the share of citations on agency ideology for each news source. For each news source, j, I run a separate OLS regression ($pct_{ij} = \beta_{0j} + \beta_{1j} I_{ij} + \epsilon_{ij}$) for each news outlet, j, and plot the resulting coefficients ($\beta_1 j$). The resulting distribution of coefficients (see Figure A14) mirrors the general pattern in the conditional estimates from the mixed-effects model, suggesting that the findings are not the artifact of a single dominant outlet. In Figure A14, the coefficients are unweighted.

Like the initial OLS results, the results of the mixed-effects model also indicate a positive relationship between agency ideology and the share of coverage from right-leaning outlets. On average, more conservative agencies cited right-leaning sources more frequently. To verify that this relationship is not limited to a few news outlets, I plot the the distribution of conditional (posterior mode) coefficients for agency ideology (see Figure A13). These coefficients are outlet-specific estimates of the effect of agency ideology, extracted from a mixed-effects model that allows both intercepts and slopes to vary by media outlet. They reflect how the ideology of an agency affects the amount of news a source publishes about that agency.

In Figure A13, nearly all of the right-leaning sources are positive, indicating that right-leaning sources publish more articles about conservative agencies, relative to liberal ones. Figure A13 also shows that left-leaning sources right-leaning publish more articles about liberal agencies, relative to conservative ones. The coefficients for center and not categorized sources are both centered close to zero. Together, these results suggest that the supply-side asymmetry is driven by both left- and right-leaning news sources.

A.4.3. Extension of Figure 5 Analysis - Leave out domains

I also recalculated the slope of the line in Figure 5 after dropping 1, 5, and 10 domains. Figure A15 shows the coefficient if 1, 5, or 10 domains are dropped from the sample. Table A6 shows how the Figure 5 coefficient changes when the largest domains (the ones with the most articles) are removed from the sample.

Table A6: Sensitivity of coefficient in Fig 5 to dropping domains

Domains dropped	Coef	N remaining	Change	Omitted domains
Five largest	0.019	864,058	0.002	nytimes, reuters, usnews, washingtonpost, yahoo
Five largest left-leaning	0.015	892,349	-0.003	cnn, nytimes, usnews, washingtonpost, yahoo
Five largest center	0.025	1,040,815	0.008	benzinga, forbes, latimes, prnewswire, reuters
Five largest right-leaning	0.013	1,117,491	-0.004	business-standard, foxnews, marketwatch, thestreet, washingtontimes

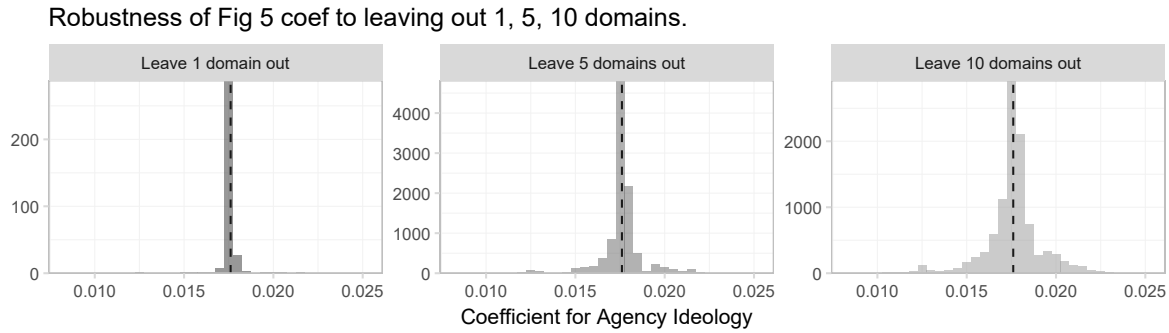

Figure A15: Distribution of coefficients after dropping 1, 5, or 10 domains. 5- and 10-domain distributions based 100,000 random samples. The dashed line is the full-sample estimate.

A.5. Matching Media Cloud to the Briefings

For the analysis in Figure 4, I match the articles in the Media Cloud dataset to the briefings. The resulting 'matched sample' contains all published articles that mention each agency name and an outcome variable that is 1 if the article is matched to the briefings and 0 otherwise. I used two different methods to match the Media Cloud results to the briefings:

1. **URL match:** If an article with the same URL (identified by EITHER option A or B below) could be found in the relevant briefing the article was counted as included. In practice, both URL matching options produce almost identical results. When matching by URL, I consider the whole briefing, not just the appropriate section. Thus, if an article mentioning US Immigration and Customs Enforcement (USICE) is placed in the "Top News" section, I count it as being included in the briefing. When determining which Media Cloud sources to include, I include any source used in the entire briefing, not just the section relevant to an agency. The DOI briefings do not contain article URLs, so this method was only possible for the VA, DHS, and USCIS briefings.

    - Option 1(A): Match by whole URL.

Table A7: Comparison of URL and Source+Date matching methods.

'Error' Type	Briefing	Total	%
'Correct' (URL match equals Source+Date match)	DHS	124,437	78.0
'Correct' (URL match equals Source+Date match)	USCIS	5,080	89.3
'Correct' (URL match equals Source+Date match)	VA	4,996	87.4
'False Negative' (URL match positive, Source+Date match negative)	DHS	5,196	3.3
'False Negative' (URL match positive, Source+Date match negative)	USCIS	53	0.9
'False Negative' (URL match positive, Source+Date match negative)	VA	151	2.6
'False Positive' (URL match negative, Source+Date match positive)	DHS	29,988	18.8
'False Positive' (URL match negative, Source+Date match positive)	USCIS	556	9.8
'False Positive' (URL match negative, Source+Date match positive)	VA	568	9.9

Table A8: Comparison of URL and Source+Date matching methods.

'Error' Type	DHS-CG	DHS-DHS	DHS-FEMA	DHS-SS	DHS-TSA	DHS-USCBP	DHS-USCIS	DHS-USICE	USCIS-USCIS	VA-VA
'Correct' (URL match equals Source+Date match)	86.6	70.0	75.3	85.4	88.6	83.0	88.1	79.3	89.3	87.4
'False Negative' (URL match positive, Source+Date match negative)	4.1	0.1	4.8	3.3	5.1	8.2	7.8	5.9	0.9	2.6
'False Positive' (URL match negative, Source+Date match positive)	9.3	29.9	19.9	11.3	6.2	8.8	4.1	14.8	9.8	9.9

- Option 1(B): Match by domain and 'slug.' The slug is defined as the longest text segment of the URL path. In practice, I first removed the query text and text following the query. I then split the text between the domain suffix and the end of the URL by forward slash. If there were multiple segments, I selected the longest one.

2. **Source+Date match:** If an article with the same news source and publication date could be found in the relevant briefing or section of briefing, all articles from that news source were counted as included. For the subagencies, I only searched for a match in their subsection of the briefing. Thus, if an article mentioning an agency name is included in another section (e.g. the 'Top news' section), it will not be counted. To reduce false positives, I removed three national news sections from the DOI briefing before matching ("TOP NATIONAL NEWS", "BIG PICTURE", "EDITORIAL WRAP-UP").

In the paper, I use the first matching strategy (URL) to generate Figure 4 because it is more accurate. Matching by Source+Date produces reasonably similar results as the URL match. To examine the accuracy of the Source+Date matching strategy, I compare the results of the matching strategies for USCIS and DHS briefings.

Table A7 shows how often the Source+Date matching strategy produced different results from the URL matching strategy. For about 20% of articles, the Source+Date strategy produces a possible 'false positive' (where the Source+Date strategy identifies a match and the URL strategy does not identify a match). Note that some of these are not true false positives because they include cases where the URL matching strategy produced a false negative. For example, if an article has multiple URLs, URL matching may undercount the number of included articles. In Figure A16 I plot the 'false positive' rate (percent of articles that are matched by the Source+Date method and not matched by the URL method) by the number of articles from each source.

Note that the 'False Negative' rate in Tables A7 and A8 is mostly an artifact of the matching process. This can occur when an article mentions a subagency's name but is included in a different section of the briefing (e.g. an article mentioning ICE is included in the 'top news' section). It can also occur when the publication date is wrong in one of the datasets. To reduce false positives for subagencies, I only considered articles from the subagency's section of the news briefing for the Source+Date matches. Table A7 shows that the 'false positive' rate is much higher for the whole briefings (DHS-DHS, USCIS-USCIS). This is because there is a higher chance that another article from the same source is included.

Figure A16 also raises another possible issue. For some audio and video media formats, the briefings provide a link to a server rather than the original source website. If the story was also posted on the source website and scraped by Media Cloud, the URL match would be incorrect. To verify that the results are not biased by the inclusion of audio and video formats, I replicate the results for Figure 4 after dropping TV and Radio media sources.

Figure A17 shows the proportion of articles missing partisan slant in the matched sample. Especially for the Source+Date match, partisan slant is missing for slightly more of the unmatched articles.

Table A9 shows the percent of the briefing articles that can be matched to Media Cloud.

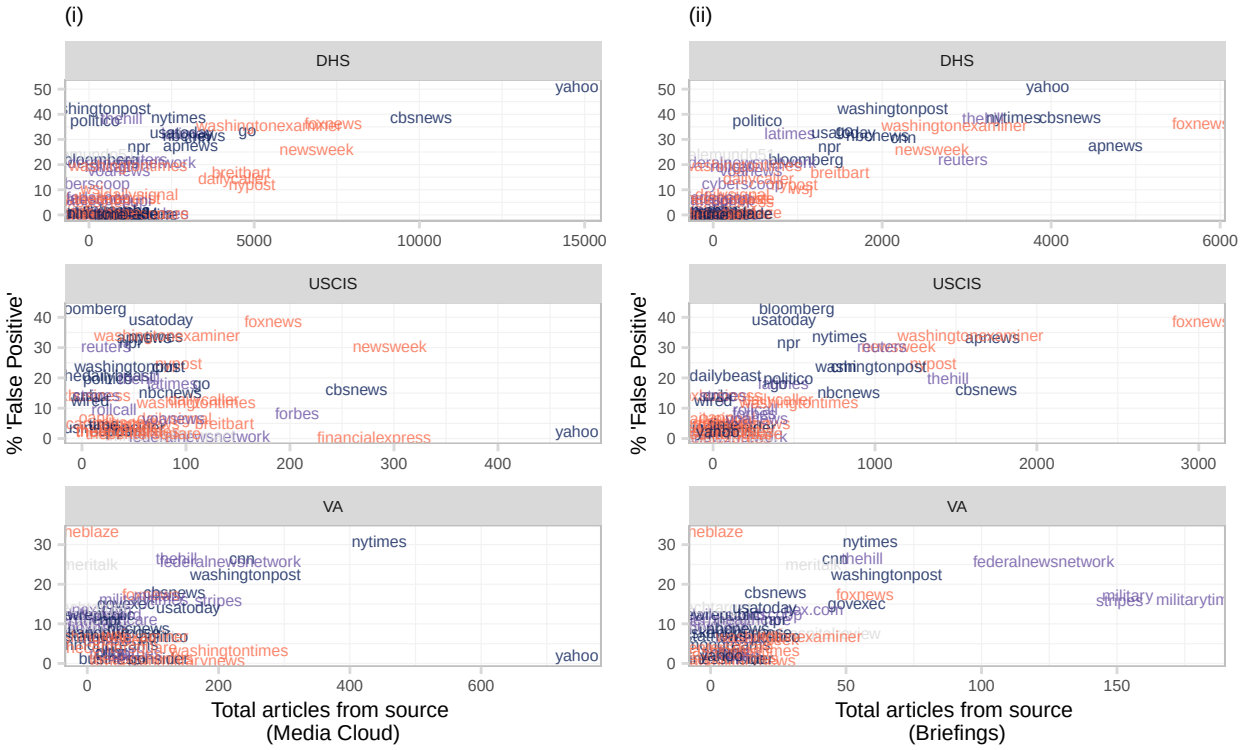

Figure A16: Association between 'false positives' (articles that are matched by the Source+Date method and not matched by the URL method) and the number of articles from each source. In subplot (i), the x-asis is the total number of articles in the Media Cloud sample from each sources. In subplot (ii), the x-asis is the total number of articles in the Briefing sample from each source.

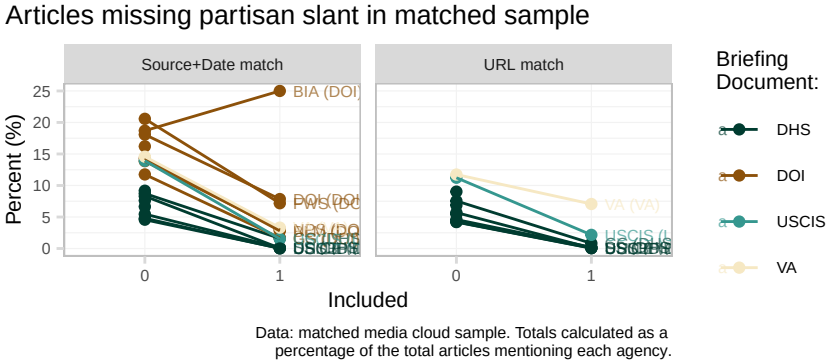

Figure A17: Percent of articles in matched sample that are missing partisan slant. In Source+Date match, dropped yahoo.com.

A.6. Testing Whether Agency Names are a Good Method for Identifying Potentially Relevant News

A.6.1. Scraping sample of DHS, USCIS, VA briefing articles

I sampled and scraped batches of 1,000-3,000 URLs from the DHS, USCIS, and VA datasets. I only sampled URLs that would be included in the Figure 3 and Figure 4 samples. In other words, I dropped government sources, local general interest sources, and non-wire international sources. I also dropped certain domains that would not contain text (e.g. youtube.com). Table A10 summarizes the proportion of sampled URLs for which the scraper recovered high-quality full text. Overall, I recovered high-quality full text for 91% of the urls that I attempted to scrape.

I used ChatGPT to develop a web scraping pipeline. Sampled briefing URLs were consolidated into a de-duplicated scrape queue and retrieved with an automated, rate-limited scraper. For each URL, the workflow saved the raw HTML and a manifest recording the retrieval date, final URL, status, error type, and other audit metadata. URLs that could not be retrieved normally were retried using archived versions from the Wayback machine and, when necessary, a separate browser-based repair pass. CAPTCHA-

Table A9: Articles from briefings that could be matched by URL to Media Cloud sample.

Agency	Briefing	Matched	Total	%
CG	DHS	854	1,727	49%
DHS	DHS	10,592	58,670	18%
FEMA	DHS	664	5,123	13%
SS	DHS	928	1,886	49%
TSA	DHS	364	1,085	34%
USCBP	DHS	1,008	3,079	33%
USCIS	DHS	274	2,341	12%
USCIS	USCIS	1,239	24,596	5%
USICE	DHS	2,398	6,075	39%
VA	VA	754	1,901	40%

Table A10: Success rate for full-text retrieval of sampled briefing URLs.

Briefing	URLs attempted	High-quality full text	Success rate
DHS	8,314	7,233	87.0%
USCIS	5,606	5,385	96.1%
VA	2,228	2,071	93.0%
Total	16,148	14,689	91.0%

protected pages were not circumvented. Successfully captured pages were then parsed with domain-specific routines and converted to structured JSON and CSV files for analysis.

I treated a web page as successfully captured when it yielded a substantial, article-like body of text rather than only a headline, brief snippet, navigation material, or an error/access page. I extracted text using several common page structures and prioritized the most article-specific version available. Pages with very short text, apparent login or paywall screens, error messages, cookie notices, video wrappers, or other non-article content were excluded. For borderline cases, I required agreement among multiple independent text-extraction methods before retaining the page.

More specifically, I extracted candidate article bodies, in priority order, from publisher JSON-LD `articleBody`, the HTML `<article>` element, `<main>`, and de-chromed page paragraphs; candidates shorter than 200 characters were not treated as credible when a longer candidate was available. A baseline extraction qualified if it contained at least 200 body characters and did not appear to be a wrong-page capture: I excluded root-domain pages and pages whose title or opening text indicated a 404/error, login or paywall, navigation, privacy/consent notice, or video wrapper. I also conservatively recovered otherwise excluded pages when at least two independent extractors (Trafilatura precision, Trafilatura recall, and Readability) each returned at least 250 characters, at least one returned 400 or more characters, and the same wrong-page screen was passed. The resulting indicator (`high_quality_full_text`) therefore denotes a credible, article-like text extraction rather than a guarantee that every word of the original article was captured.

A.6.2. Keyword hit rates

In this section, I discuss the "keyword hit rate," or the share of articles that contain at least one of the agency name keyword queries. First, I discuss hit rate for the successfully-scraped articles with high quality full text. I then use the briefing summary text to estimate a minimum hit rate for the DOI briefings. I also use the full text articles provided in the VA briefing ("briefing-full-text") to validate the scraped article results ("html-full-text").

Scraped Full Text—Table A11 summarizes html-full-text results by agency. Tables A12 and A13 shows how hit rates vary across briefing sections. In Tables A12 and A13 the columns represent the keyword queries for each subagency. Thus, the CG column is the hit rate for "Coast Guard," the DHS column is the hit rate for "Homeland Security," etc.

Table A11 shows that agency names appear in more than half of articles for most briefings and subsections. There are three exceptions: FEMA, DHS, and USCIS.

First, FEMA is only found in 24% of the FEMA-section articles, which reflects FEMA's policy portfolio. The FEMA section also contains coverage of major weather events that could become national disasters. Due to Media Cloud quota restrictions, I did not attempt to query all major weather events.

Second, only 29% of the articles in the DHS briefing contain the term "Homeland Security." The hit rate increases to 49% after adding the subagency names. Table A12 reveals which DHS sections are less captured by the agency keywords. CISA/Cybersecurity is low partially because the relevant agency name (Cybersecurity and Infrastructure Security Agency) is not included in this version of the keywords because CISA is not scored by Richardson et al. (2018). However, even when I add it to the list of expanded DHS

Table A11: Agency-name hit rates in high-quality full-text extractions.

Document	Agency / briefing	Scraped full text	Name hits	Hit rate
DHS section	Coast Guard	191	178	93%
DHS section	FEMA	601	146	24%
DHS section	Secret Service	258	191	74%
DHS section	TSA	139	92	66%
DHS section	Customs and Border Protection	464	231	50%
DHS section	USCIS (DHS section)	317	66	21%
DHS section	Immigration and Customs Enforcement	825	455	55%
DHS whole briefing	DHS (DHS name only)	7,170	2,045	29%
DHS whole briefing	DHS (with subagencies)	7,170	3,487	49%
USCIS (whole briefing)	USCIS	5,299	442	8%
VA (whole briefing)	Veterans Affairs	2,061	1,658	80%

Table A12: Agency-name hit rates by DHS briefing section. Entries are percentages of high-quality full-text extractions. Asterisks indicate that multiple, similar headings were combined.

		Percent of URLs with a name hit								
Section	URLs	Any agency	CG	DHS	FEMA	SS	TSA	CBP	USCIS	ICE

Top News	1,609	55%	1%	47%	1%	0%	0%	12%	4%	13%
USCIS In The News	274	79%	0%	36%	0%	0%	0%	8%	73%	11%
Total	**5,299**	**51%**	**1%**	**34%**	**1%**	**0%**	**0%**	**14%**	**8%**	**15%**

queries (see A.10, Table A19), I get a relatively low hit rate (38%) compared to other section headings. Additionally, "Terrorism Investigations" has a low hit rate. Presumably, this section is frequently updated to include terms that capture recent terror attacks and ongoing investigations.

Third, the hit rate for USCIS is also lower. 21% of articles in the USCIS section of the DHS briefing mention USCIS by name. This is still higher than the hit rate for the USCIS briefing. Only 8% of the articles in the USCIS briefing mention USCIS by name. Tables A12 and A13 help to explain the lower hit rate for USCIS. The columns indicate what percent of the articles in a section of the DHS/USCIS briefing contain the names of a DHS subagency. Compared to related agencies, USCIS gets less news coverage. Much of the USCIS content, particularly in the USCIS briefing, mentions other immigration agencies like DHS, USICE, and USCBP. 51% of the USCIS briefing mentions USCIS, DHS, or one of the other DHS subagencies.

Summary-based estimates—Because links were not preserved in the DOI pdfs, I could not scrape the html files to estimate the full text keyword hit rates. However, I can estimate a *minimum* hit rate based on how often each keyword query appears in the summary. For this analysis, I also drop government sources, local general interest sources, and non-wire international sources.

As discussed in the background section of the paper, the DOI, USCIS, and DHS briefings often combine multiple articles into a single 'story.' I search the just the summary text associated with an article. Thus, if an article is not summarized and is listed as 'also covered in…', it is dropped. I do not search the story title because I could not reliably extract the title for the DOI section. Because the USCIS and DHS briefings are .docx files with consistent styles, I could reliably split the briefings into stories. The VA briefings summarize each article, so I searched each article's summary separately.

Compared to the other briefings, parsing the DOI pdfs was more complicated and prone to errors. As a result, the summary-identification method may underestimate the hit rate compared to the USCIS and DHS briefings. For articles that were summarized, I searched the text of the paragraph where the citation appeared. Sources that were not summarized are dropped. Because some summaries are multiple paragraphs, this may underestimate the DOI hit rate, but due to OCR issues and formatting inconsistencies, I could not reliably split the articles by story. The vast majority of story summaries are a single paragraph.

For consistency across DOI briefings, I standardized a small number of headings that referred to the same substantive section. For example, "DOI News" was coded as DOI IN THE NEWS; "U.S. Geological Survey" and "US Geological Survey" were standardized as US Geological Survey; "Office of Insular Affairs," "Office of Insular and International Affairs," and "Insular and International Affairs" were combined as OFFICE OF INSULAR AFFAIRS; "Office of Surface Mining" was standardized to Office Of Surface Mining Reclamation And Enforcement; and "Opinion" was combined with Opinion Pieces.

Table A14: Agency-name hit-rate estimates from scraped full text, briefing summaries, and VA briefing full text.

	Hits / records (percent with an agency-name hit)		
Agency / briefing	HTML full text	Briefing summary	VA briefing full text
DHS (with subagencies)	3,487/7,170 (49%)	10,963/37,193 (29%)	-
DHS (DHS name only)	2,045/7,170 (29%)	5,551/37,193 (15%)	-
USCIS (DHS briefing)	66/317 (21%)	144/1,290 (11%)	-
USCBP	231/464 (50%)	822/2,192 (38%)	-
USICE	455/825 (55%)	1,442/2,883 (50%)	-
FEMA	146/601 (24%)	550/3,516 (16%)	-
SS	191/258 (74%)	727/1,275 (57%)	-

-	**Total (less top national news and editorial wrap-up)**	**1,103**	**20%**	**1%**	**2%**	**1%**	**11%**	**3%**	**1%**	**4%**

Table A14 compares the html-full-text hit rates to the summary text hit rates. Because the summaries do not always repeat the agency name, the summary hit rate is lower than the html-full-text rate. In some cases, the summary hit rate is much lower than the

html hit rate. 80% of the scraped full text VA articles contain the agency name. For about half of these articles, the summary does not contain the agency name. Typically, the summary hit rate underestimates the html hit rate by about 10-20 percentage points. The full USCIS briefing is an outlier; the summary rate is slightly higher than the full-text rate. This is partly because the html sample excludes certain kinds of articles that have summaries, including articles that could not be scraped and TV/audio news on video-hosting platforms. In a small number of cases, summaries use the full agency name while the cited article uses the acronym.

Table A15 shows the hit rate for each DOI agency name in each section of the DOI summary. Note that the DOI summary contains two sections dedicated to national news. If those sections are included, the summary hit rate for the DOI briefing is lower (8%) than a comparable agency like DHS (29%). However, it goes up to 20% if the national sections are dropped.

Most likely, the summary hit rate is a larger underestimate for DOI. The biggest indicator is the "DOI in the news" section. Only 22% of the "DOI in the news" articles contain the agency name keywords. Even with the expanded queries —which include all of DOI subcomponents and agency leader names—the "DOI in the news" section summary hit rate is still suspiciously low (28%) (see A.10, Table A22). In comparison, the html hit rate for "Citizenship and Immigration Services" in the "USCIS in the news" section is 73%. Additionally, if a story summary was split into multiple paragraphs, the summary variable for the DOI briefings contains less story text than the equivalent variables for DHS and USICS.

VA-briefing Full Text—In addition to a short summary, the VA briefings also include the full text of the article at the end of the pdf. To validate my html-full-text estimate, I extract and search the full text and article title from the VA briefing. To make the sample consistent, I restrict the briefing-full-text estimate to the URLs that I attempted to scrape, including the 7% of the sample that I did not successfully scrape. Table A14 compares the html-full-text estimate to briefing-full-text estimate. It shows that the html- and briefing-full-text estimates are similar.

A.6.3. Comparing articles with and without agency-name keywords

Figures A18 and A19 reveal that the relationship between agency ideology and media slant is stronger in the set of articles that contain an agency's name. Figure A18 reproduces the right-leaning subplot of Figure 1 using all of the successfully scraped articles, the scraped articles with agency-name query hits, and the scraped articles without query hits. Figure A19 reproduces the right-leaning subplot of Figure 1 using all of the briefing articles, the briefing articles with summaries that contain agency-name query hits, and the articles without summary hits. Because the summary-hit-rate is an underestimate, Figure A19 likely underestimates the difference between the articles with agency names and the articles without agency names.

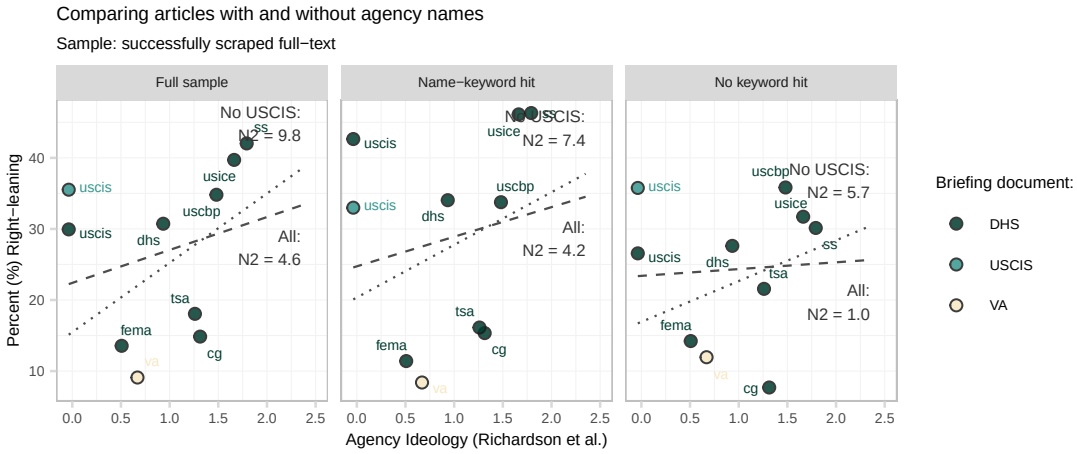

Figure A18: Representativeness of articles that contain agency names (scraped full text sample). Relationship between agency ideology and right-leaning media slant for whole sample, articles that contain agency names, and articles without agency names. Sample is restricted to scraped articles with high-quality full text.

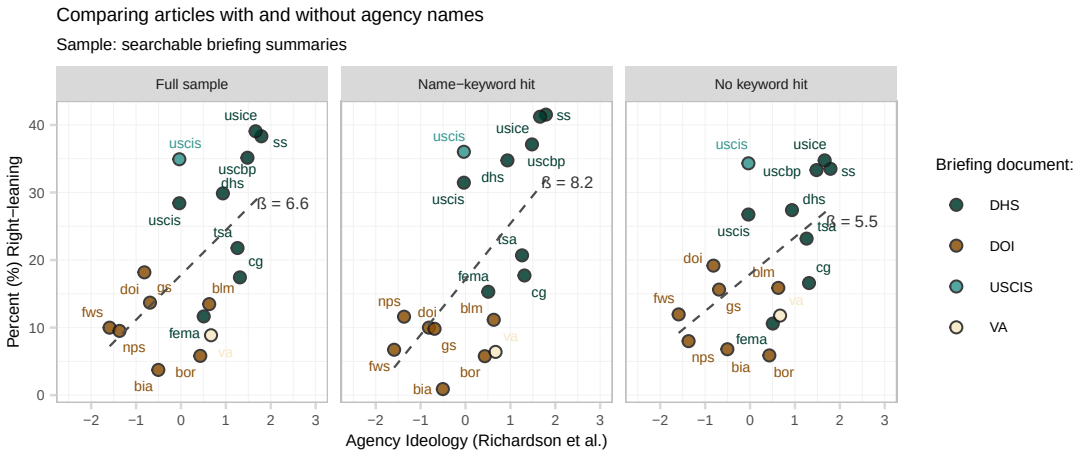

Figure A19: Representativeness of articles that contain agency names (estimated from summaries). Relationship between agency ideology and right-leaning media slant for whole sample, articles with summaries that contain agency names, and articles with summaries that do not contain agency names. Dropped government, local general interest, and non-wire international sources. Dropped articles without summaries.

A.6.4. Representativeness of Media Cloud sample

How complete is the Media Cloud database? Table A16 shows the percent of confirmed keyword hits in the scraped sample of DHS, USCIS, and VA briefing articles that can be matched to Media Cloud. If Media Cloud contains all articles from the briefings, the last column would be 100%. Instead, Media Cloud contains about 60% of the articles with agency names.

Table A16: Articles with agency name keywords from scraped sample that could be matched by URL to Media Cloud sample.

Briefing	Agency	Total Scraped with Keyword Hit	Matched to Media Cloud	%
DHS	CG	173	86	49.7%
DHS	DHS (DHS only)	2,051	1,292	63.0%
DHS	DHS (DHS+subagencies)	3,482	2,150	61.7%
DHS	FEMA	137	51	37.2%
DHS	SS	193	132	68.4%
DHS	TSA	92	43	46.7%
DHS	USCBP	197	129	65.5%
DHS	USCIS	68	48	70.6%
DHS	USICE	458	325	71.0%
USCIS	USCIS	395	254	64.3%
VA	VA	1,387	642	46.3%
Total	Total	8,633	5,152	59.7%

Table A17: Representativeness of Media Cloud news collection

Notes: Dataset includes all scraped DHS, USCIS, and VA URLs that contain an agency-name keyword. DV is the 1 if the URL is found in the Media Cloud output for the agency-name, 0 otherwise. Standard errors clustered by media domain, agency, and URL.

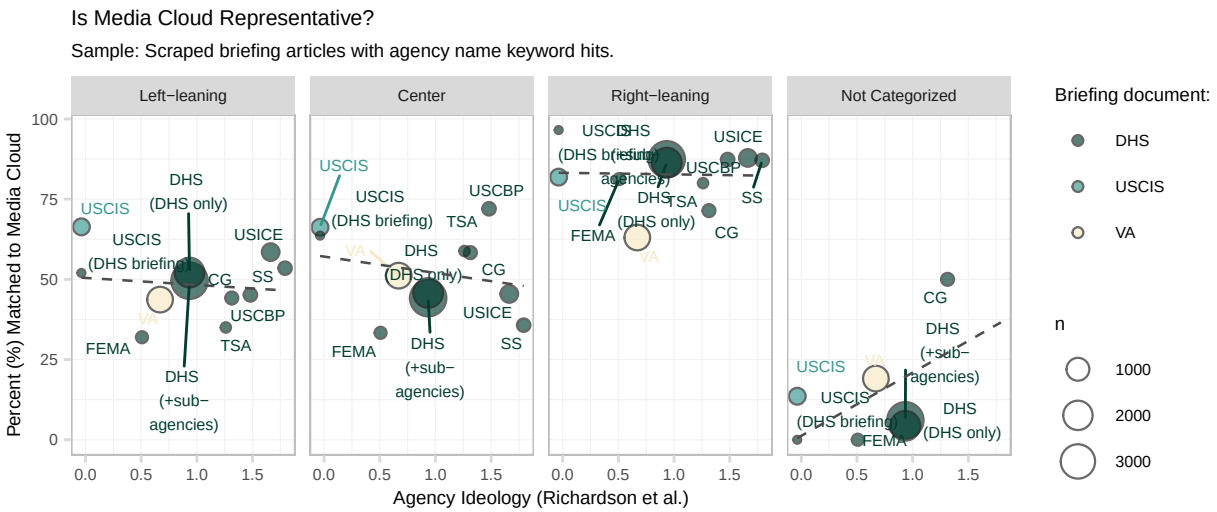

Figure A20: Representativeness of Media Cloud news collection by agency ideology. Dataset includes all scraped DHS, USCIS, and VA URLs that contain an agency-name keyword. Limited to domains collected by Media Cloud. Article is 'Matched to Media Cloud' if its URL is found in Media Cloud output for the agency.

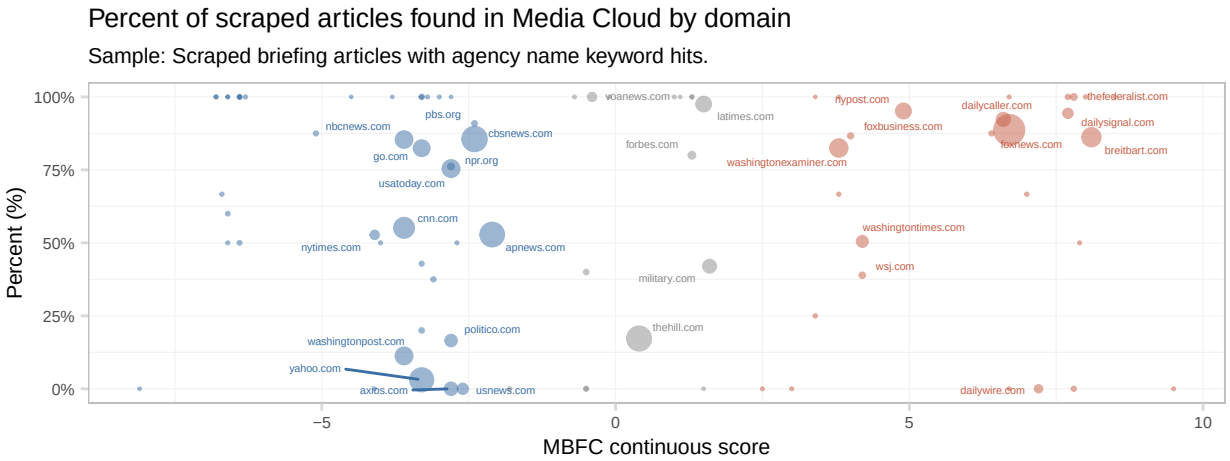

Figure A21: Representativeness of Media Cloud news collection by domain. Dataset includes all scraped DHS, USCIS, and VA URLs that contain an agency-name keyword. Limited to scraped articles from domains collected by Media Cloud. Article is counted as 'Matched to Media Cloud' if the URL is found in the Media Cloud output.

Is Media Cloud news collection biased? Unless Media Cloud news collection is correlated with the interaction between agency ideology and news source slant, its incompleteness should not affect my results. To test for biased collection, I look at the relationship between these variables and Media Cloud collection among articles that contain agency names. I take the sample of articles that I successfully scraped and filter it to only include articles that contain agency-name keywords. For each agency name, I add a variable that is 1 if the URL is found in the Media Cloud output for that agency and 0 otherwise. In Table A17, I regress the Media Cloud indicator on agency ideology, news slant, ideology*slant.

Table A17 and Figures A20 and A21 strongly suggest that Media Cloud does a better job collecting right-leaning news sources for the set of domains and dates in the scraped DHS, USCIS, and VA briefing articles. If Media Cloud has better coverage for right-leaning sources, the size of the slope in Figure 3 could be magnified, but only if news sources asymmetrically produce news about ideologically-aligned agencies. If news production was uncorrelated with agency ideology and source slant, Media Cloud's more comprehensive collection of right-leaning sources could result in an intercept shift, but it would not affect the slope.

Figure 5 could also be affected; however, the scraped articles are a worse test for the Figure 5 sample because it includes a larger time period and set of domains. For Figure 5, I sampled dates from 2015-2025 and included all domains in any of the four briefing documents. After dropping NA media slant domains, only 136 domains appear in both the scraped sample and the Media Cloud sample whereas the Figure 5 sample contains 334 sources. Because the DHS, USCIS, and VA briefings do not include all domains in the DOI briefings and only cover 2020-2025, I cannot confirm that Media Cloud also collected more right-leaning news

during the earlier period and larger set of domains. When I reproduce Figure 5 with only the weeks from 2015-2019, the coefficient between agency ideology and right-leaning slant is positive, similar sized, and statistically significant (see Figure A10). There is also a statistically significant positive slope when I used a different media database (GDELT) instead of Media Cloud.

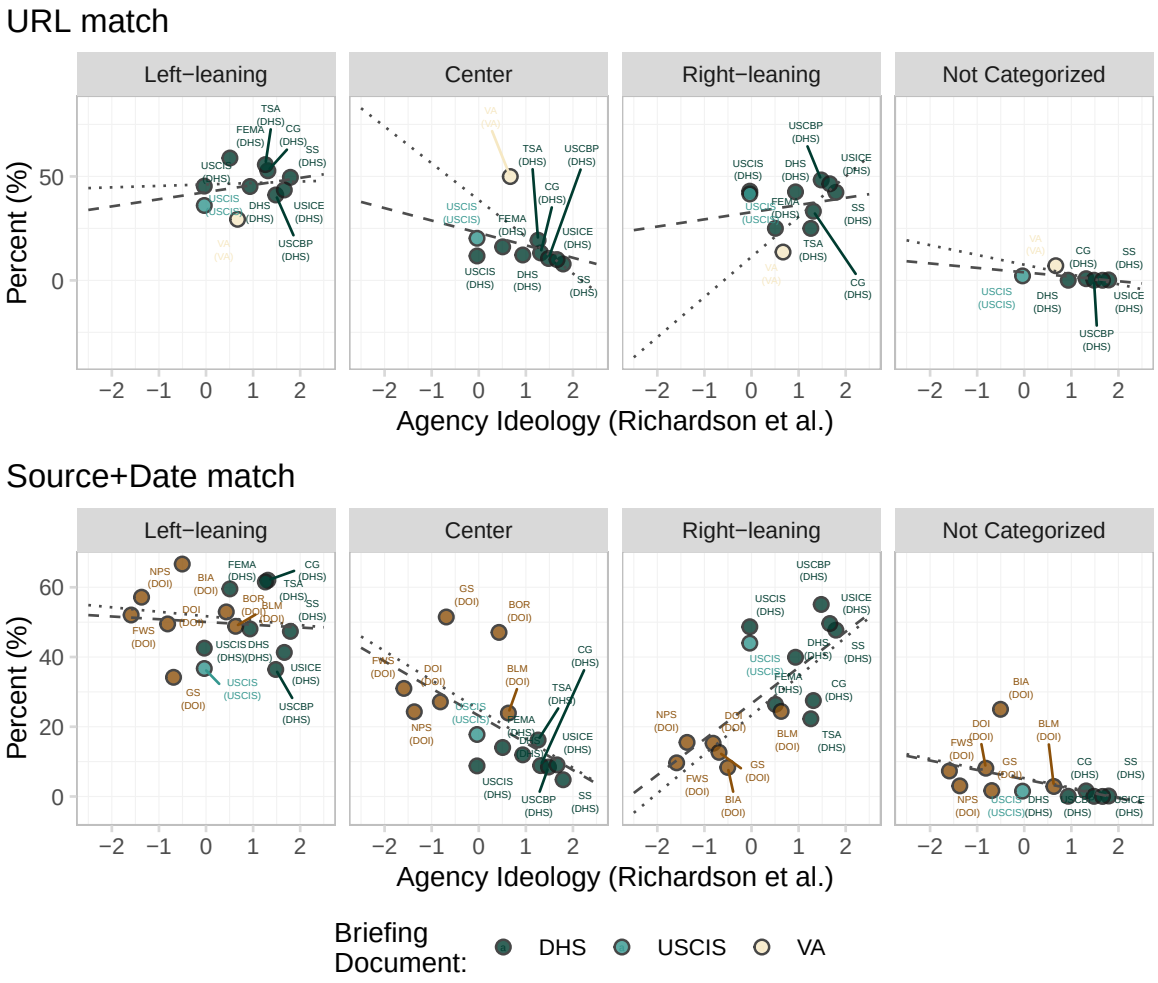

Figure A22: Replication of Figure 1 using articles matched to the briefing dataset. The top row uses URL matching; the bottom row uses Source+Date matching. The dotted line excludes USCIS.

Does the Fig 1 skew appear in the briefing articles found in Media Cloud? - In order for Figure 4 and the the analyses in A.7 to be meaningful, the skew in Figure 1 must appear in the subset of articles that both (1) contain an agency name and (2) are matched to Media Cloud. In Figure A22, I show that this is the case. The upper plot replicates Figure 1 using only the articles from the briefings that were matched to the briefing sample by URL. The lower plot replicates Figure 1 using only the articles from the briefings that were matched to the briefing sample by Source+Date.

A.7. Figure 4 - Biased Selection

Formally, to test whether the slant of an outlet still affects its inclusion after accounting for supply, I use the following model: $Incl_i = \beta_0 + \beta_1 S_i + \beta_2 I_i + \beta_3 (S_i \times I_i) + \epsilon$. For each article i, $Incl_i$ is 1 if the article is included in the briefing, S_i is the slant of the news outlet, and I_i is the ideology of the agency mentioned in the article. If agencies are preferentially selecting articles from ideologically-aligned sources, the interaction between agency ideology and right-leaning slant would be positive. In contrast, the results suggest a weak, possibly negative relationship across multiple specifications.

1. First, I vary the matching method. In Figure A26, I replicate Figure 4 using the Source+Date matched sample. The coefficients are noisier, likely because the Source+Date matching strategy is less accurate and produces more false matches. Although imperfect, the strategy is available for all four sets of briefings. While the coefficients are noisier, there is still no positive relationship between agency ideology and partisan slant. Figures A25, A23, A24 show results for both matching strategies.

2. Second, I vary the measures of media slant and agency ideology. In Figures A23 and A24, I test the following alterations:

- Replace Richardson et al (2018) agency ideology scores with scores from Napolio (2025).
- In Figure A23, I replace MBFC partisan slant measures with ones from Allsides; Bakshy, et al. (2015); and Robertson, et al. (2018).[4] I also test a version of the MBFC with the center and left-leaning sources both combined into a single center/left reference category.
- In Figure A24, I replace categorical partisan slant measures with continuous ones from MBFC; Robertson, et al. (2018); and Bakshy, et al. (2015). Continuous scores are rescaled to between 0 and 1.

3. Third, I vary the sample. In Figure A25, I test the following alterations:

- Keep/Drop Yahoo - Depending on the matching strategy, I show what happens when I add or drop Yahoo.com. For the Source+Date match, I keep Yahoo. For the URL match, I drop Yahoo.
- Only Print - I drop all TV and Radio sources. Some TV/radio sources have links to 3rd party hosting services instead of a text article, so I cannot match as many radio and tv citations to the Media Cloud data by URL.
- Expanded Domains - By default, I keep only domains that are cited at least once by the company that produces each briefing.[5] In this alternate specification, I include Media Cloud articles if the domain was cited in any of the briefings (DOI, VA, DHS, and USCIS).
- Add Local+Gov - I add back local general interest sources and government websites.
- Add Local+Gov+Int - I add back local general interest, government, and international sources.
- Drop Apr-Nov'25 - I drop all articles published after April 1, 2025.
- Keep NA slant - I add back sources with missing slant scores, treating NA slant as a category of media slant.
- Drop wire sources - I drop articles from wire sources.
- Drop sources with zero matches - I drop sources that are not successfully matched to the briefing at least once.
- Drop USCIS - I drop articles from the USCIS briefing and USCIS section of the DHS briefing.

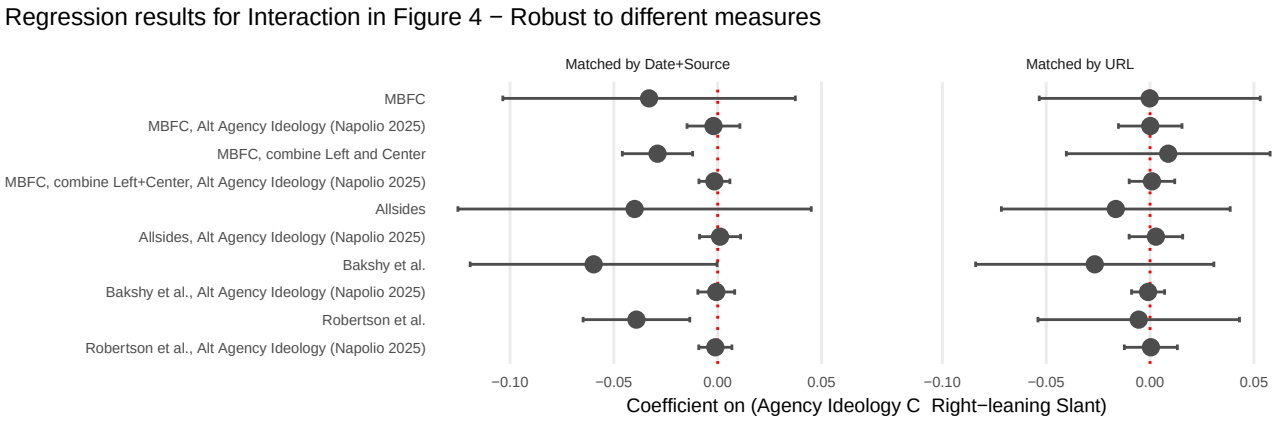

Figure A23: Robustness of interaction effect in Figure 4 to different measures.

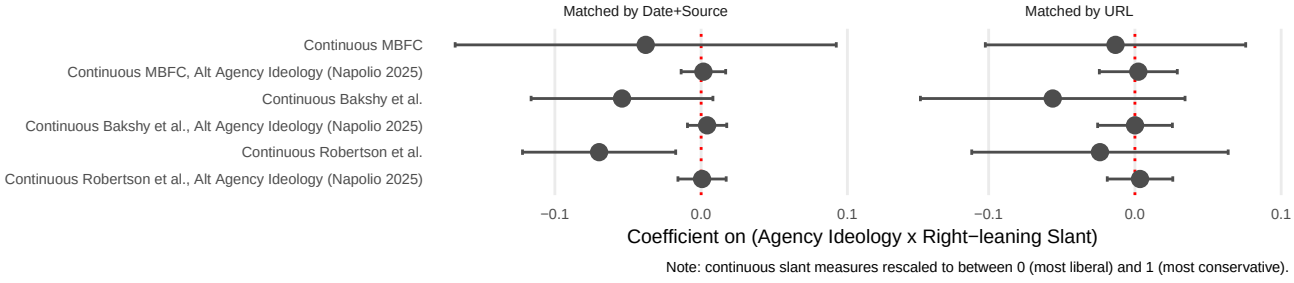

Figure A24: Robustness of interaction effect in Figure 4 to continuous measures of partisan slant.

[4] I convert all scores to a 3-category scale (Left-leaning, Center, Right-leaning) to make the results more comparable.

[5] Thus, for the DOI, FWS, NPS, etc Media Cloud results, I only keep articles from sources cited in the DOI briefing. For the VA Media Cloud results, I keep sources cited in the VA briefings. For the USCIS and DHS, I keep articles from sources cited in either briefing because they are produced by the same vendor.

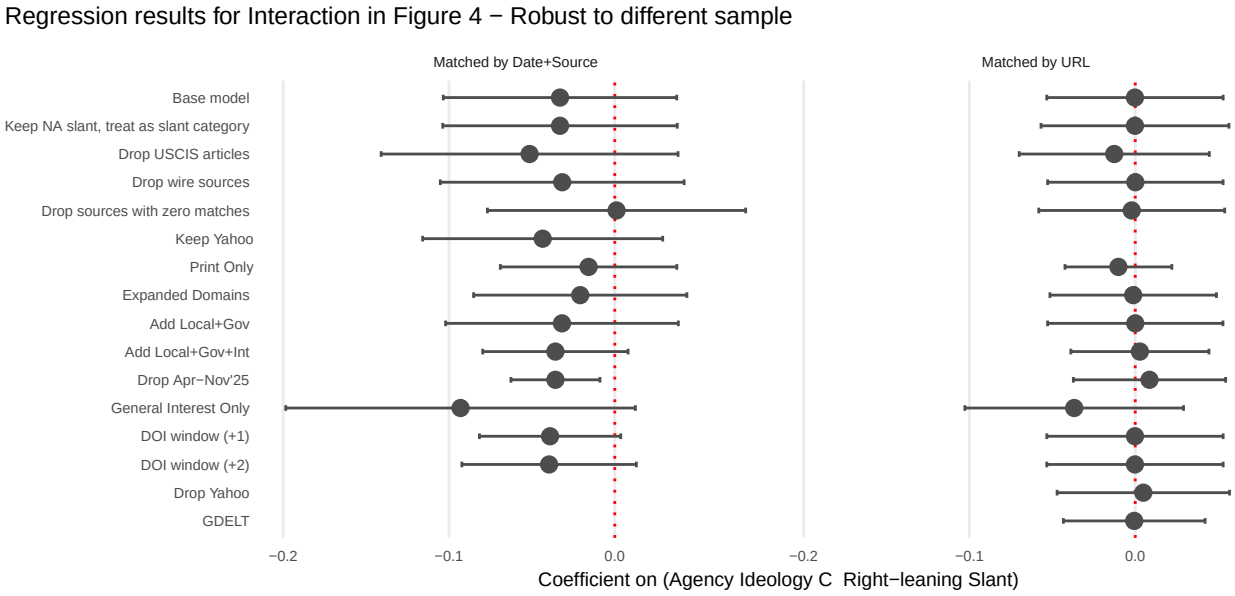

Figure A25: Robustness of interaction effect in Figure 4 to different samples.

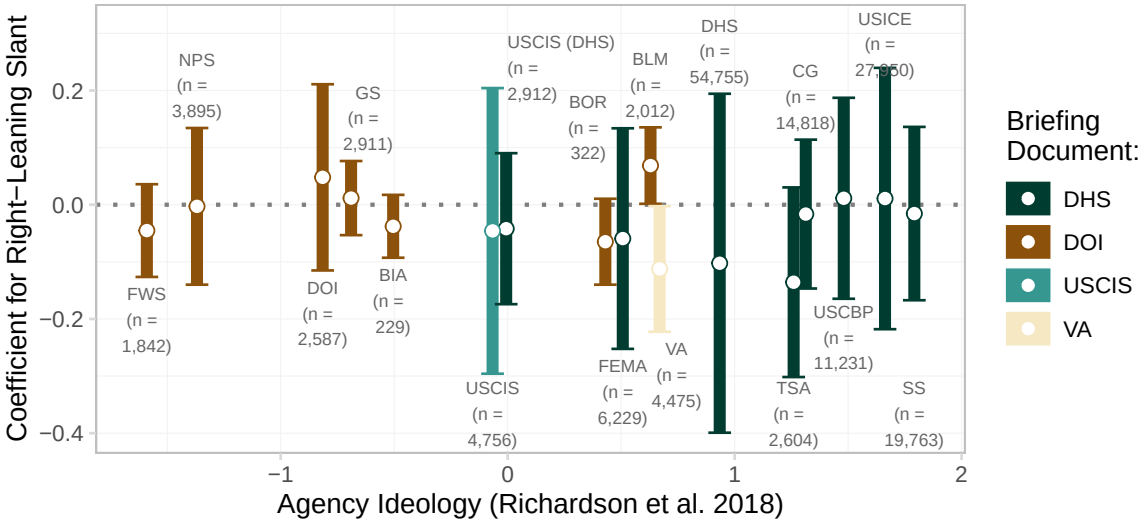

Figure A26: Alternate specifications for Figure 4 - Matched by Source+Date.

A.8. Figure 6 - Over-time partisan slant of sources

Over time partisan slant—Figure A27 produces a version of Figure 6 for the other three briefings. The next set of plots demonstrate the robustness of the pattern in Figure 6. Figure A28 reproduces Figure 6 after adding back local general interest news and government websites. Figures A29, A30, and A31 reproduce Figure 6 using alternative categorical media slant measures. Figures A32 and A33 reproduce Figure 6 using alternative continuous media slant measures.

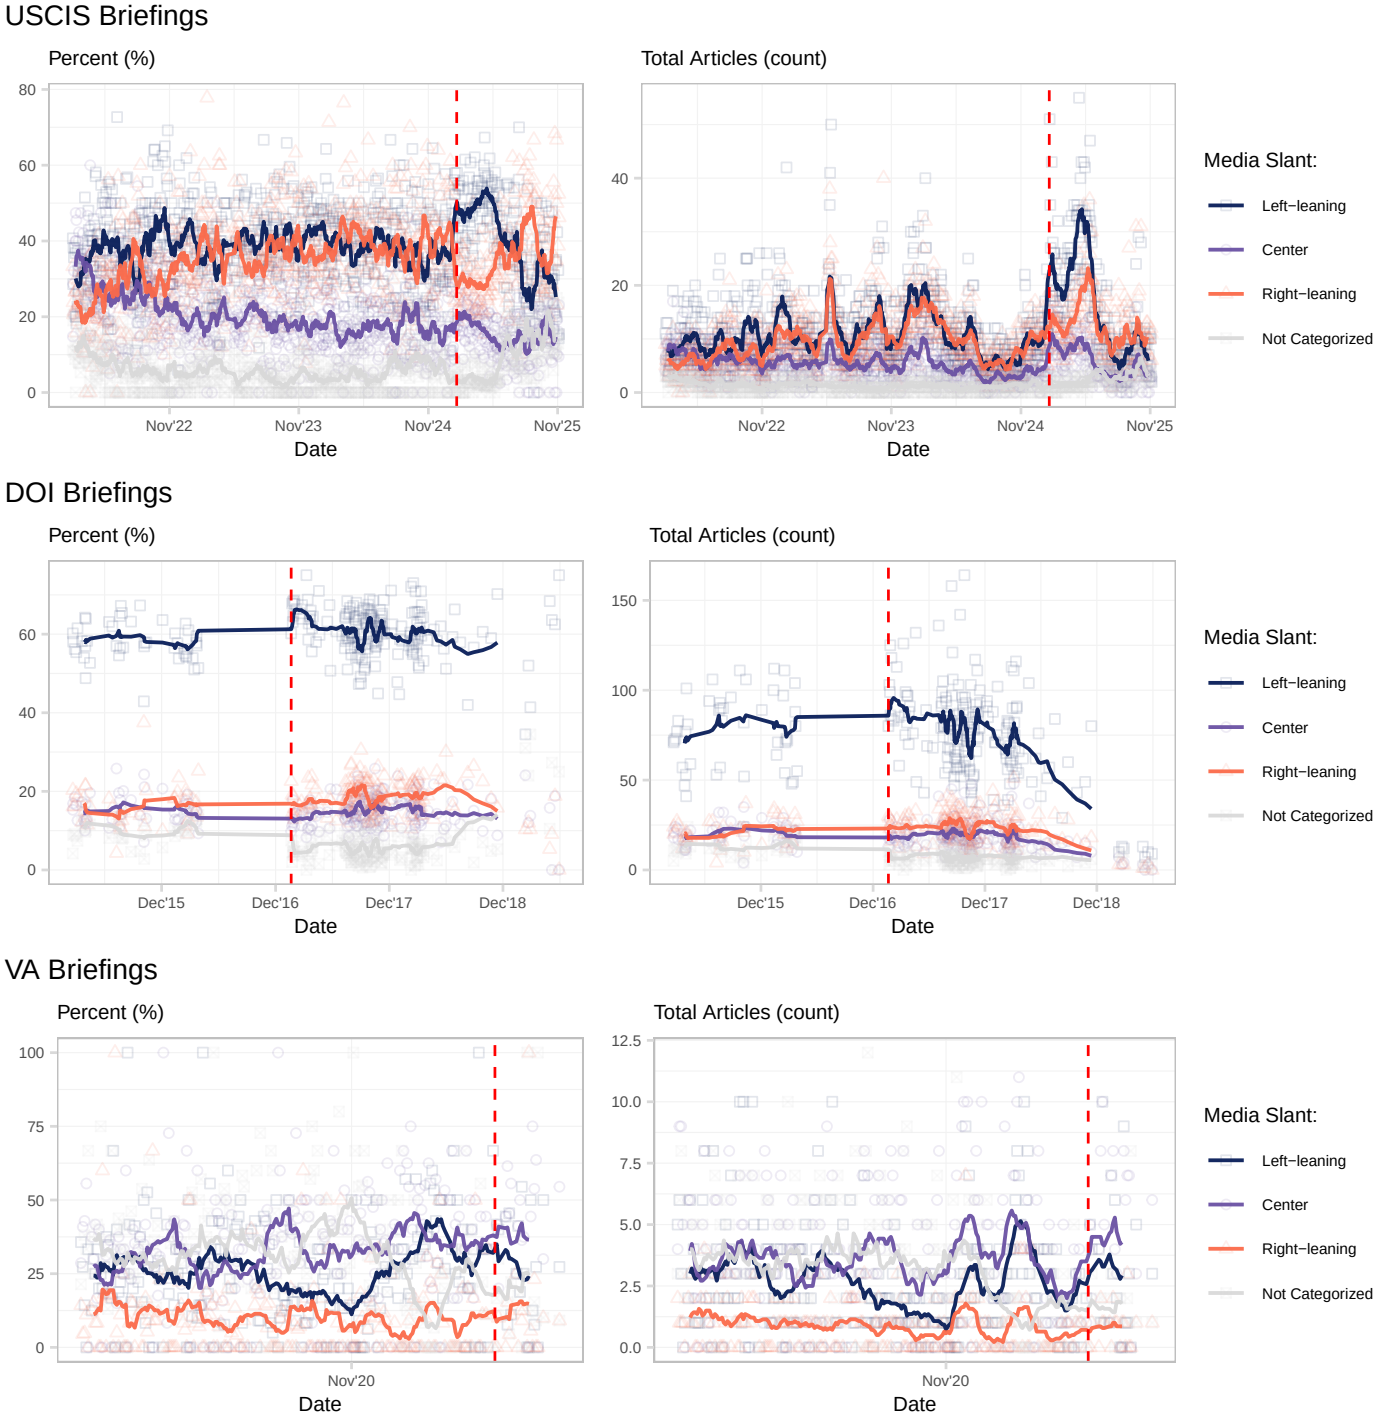

Figure A27: Over-time coverage from partisan sources in the USCIS, VA, and DOI news briefings. Articles from general interest local news sources and government websites are excluded. Partisan media scores from Media Bias Fact Check (MBFC). Dotted line at presidential inauguration. Lines are 14-day rolling averages.

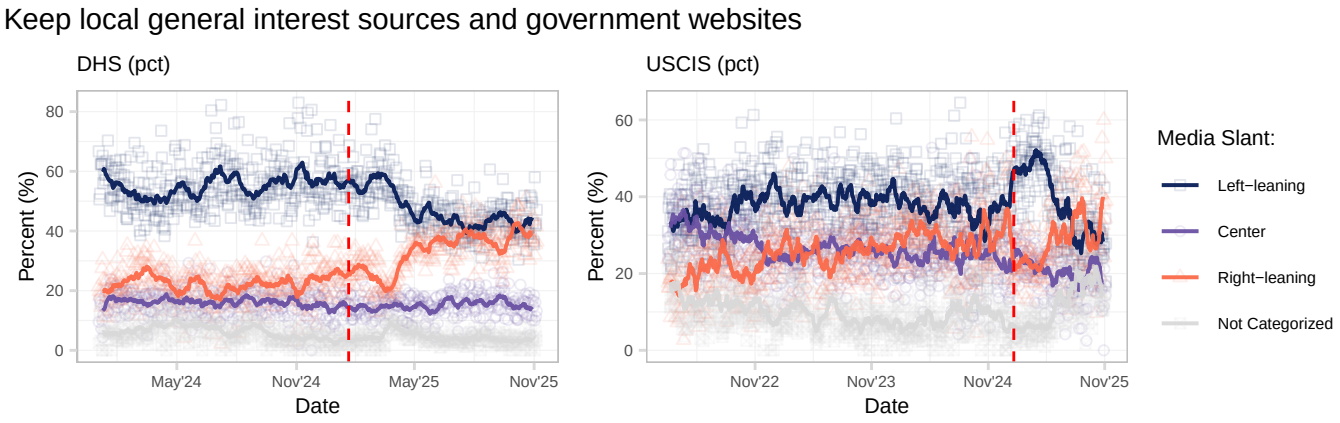

Figure A28: Alternate specifications for Figure 6 - Keep local general interest sources and government websites.

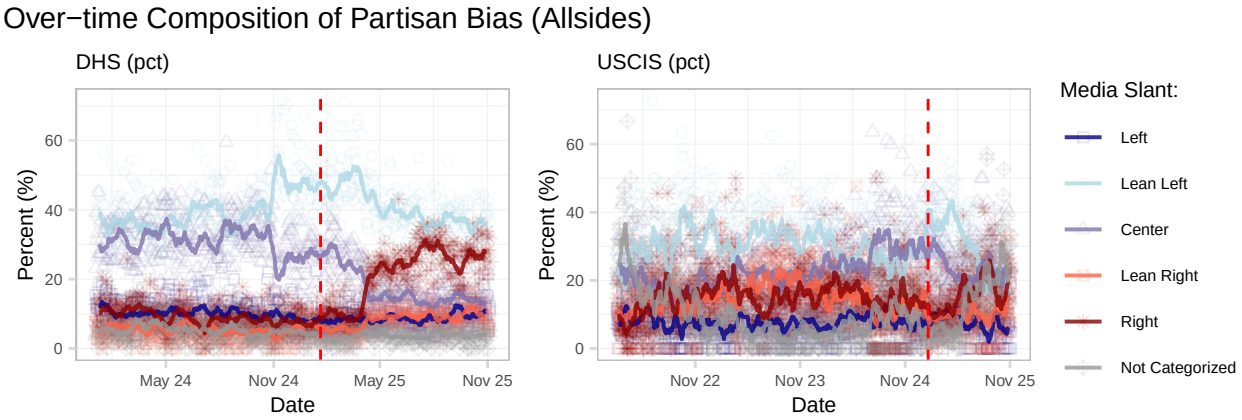

Figure A29: Alternate specifications for Figure 6 - Allsides partisan slant scores. Lines are 2-week rolling averages.

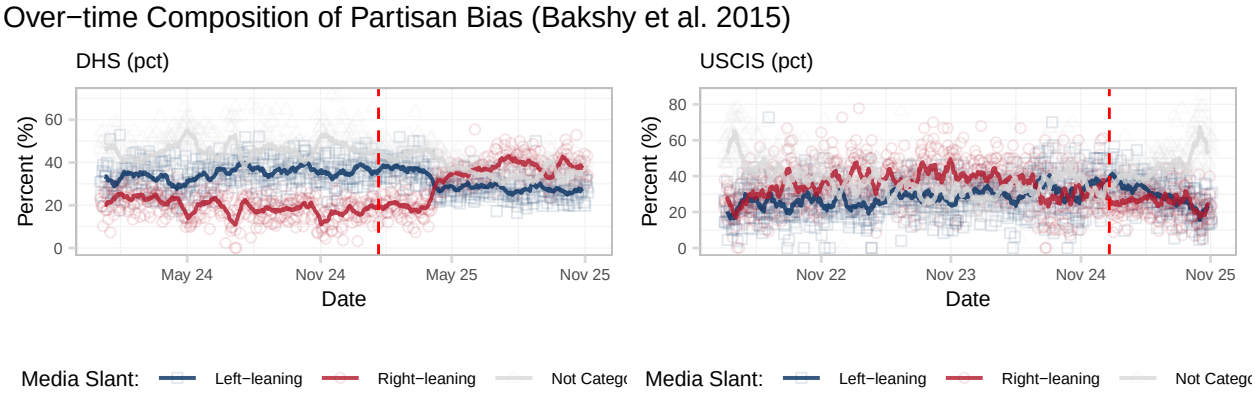

Figure A30: Alternate specifications for Figure 6 - Bakshy, Messing, and Adamic (2015) partisan slant scores. Left/Right-Leaning categories combined with Left/Right categories. Lines are 2-week rolling averages.

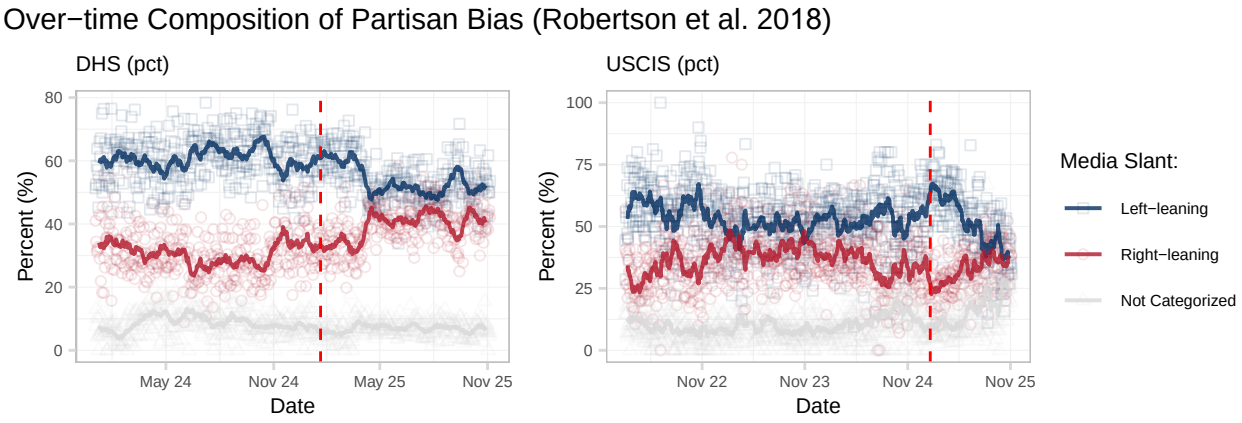

Figure A31: Alternate specifications for Figure 6 - Robertson, Lazer, and Wilson (2018) partisan slant scores. Left/Right-Leaning categories combined with Left/Right categories. Lines are 2-week rolling averages.

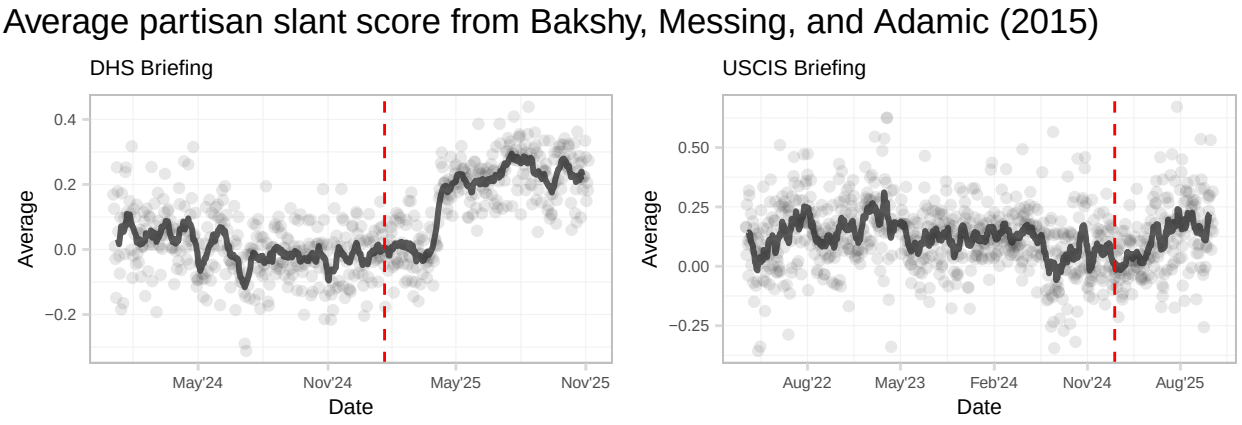

Figure A32: Average partisan bias score from Bakshy, Messing, and Adamic (2015) Lines are 2-week rolling averages.

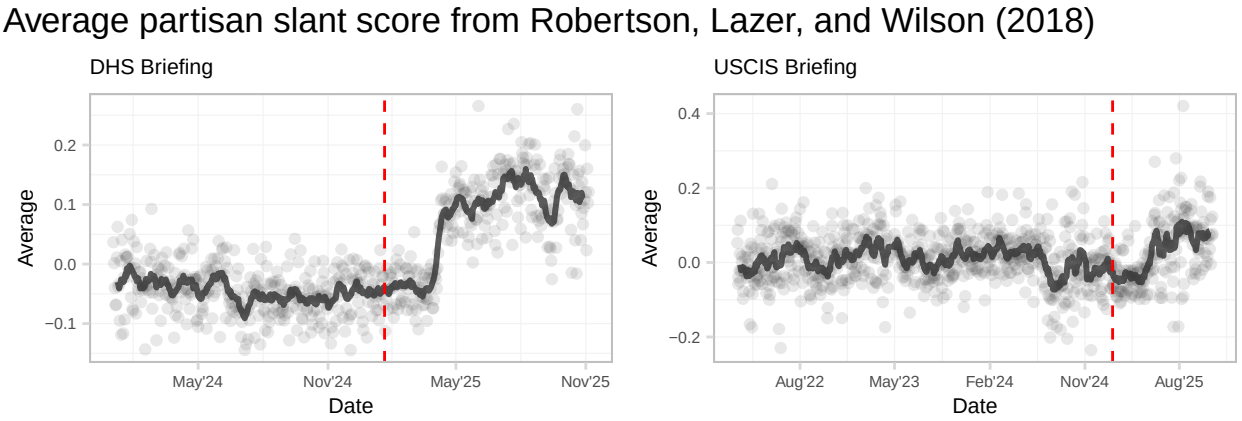

Figure A33: Average partisan bias score from Robertson, Lazer, and Wilson (2018). Lines are 2-week rolling averages.

Sources added to briefings by partisan slant and extremity—To visualize how the composition of the DHS and USCIS briefings changed in early 2025, I identified sources that Media Bias/Fact Check considered extreme. To do this, I used a continuous version of the MBFC score.[6] Continuous scores are only available for 48.4% of the sources in the briefings, which is why I use the categorical version elsewhere. The continuous scores range from -10 (most left-leaning) and 10 (most right-leaning). I labeled

[6] After dropping local general interest source, government websites, and sources not found in any briefing, the continuous values range from -9.6 to 9.8. The mean is -0.32 and the median is -1.2. The standard deviation is 4.8.

scores as extreme if they were above 5 or below -5. If the source did not have a continuous score, I labeled it as 'unknown.' In Figure A34, I plot the number of new sources appearing in the briefings by month. Sources are only counted if they have never been included in the briefing previously. I break down sources by their MBFC categorical score and extremity.

Figure A34 shows that an abnormally large number of extreme right-leaning sources were added to the DHS and USCIS briefings around April 2025. Even though the overall composition of the USCIS briefings was less affected, Figure A34 reveals how far-right sources were added to both briefings. The plot also illustrates how this influx of partisan sources deviates from prior time periods. When I produce similar plots for the DOI or VA briefings, the pattern of added sources is stable across presidential transitions. I also explored the spike in new 'not categorized' sources after Trump's inauguration. Because each of these sources contributes a small number of articles to the briefings, they represent a small change to the composition of both briefings.

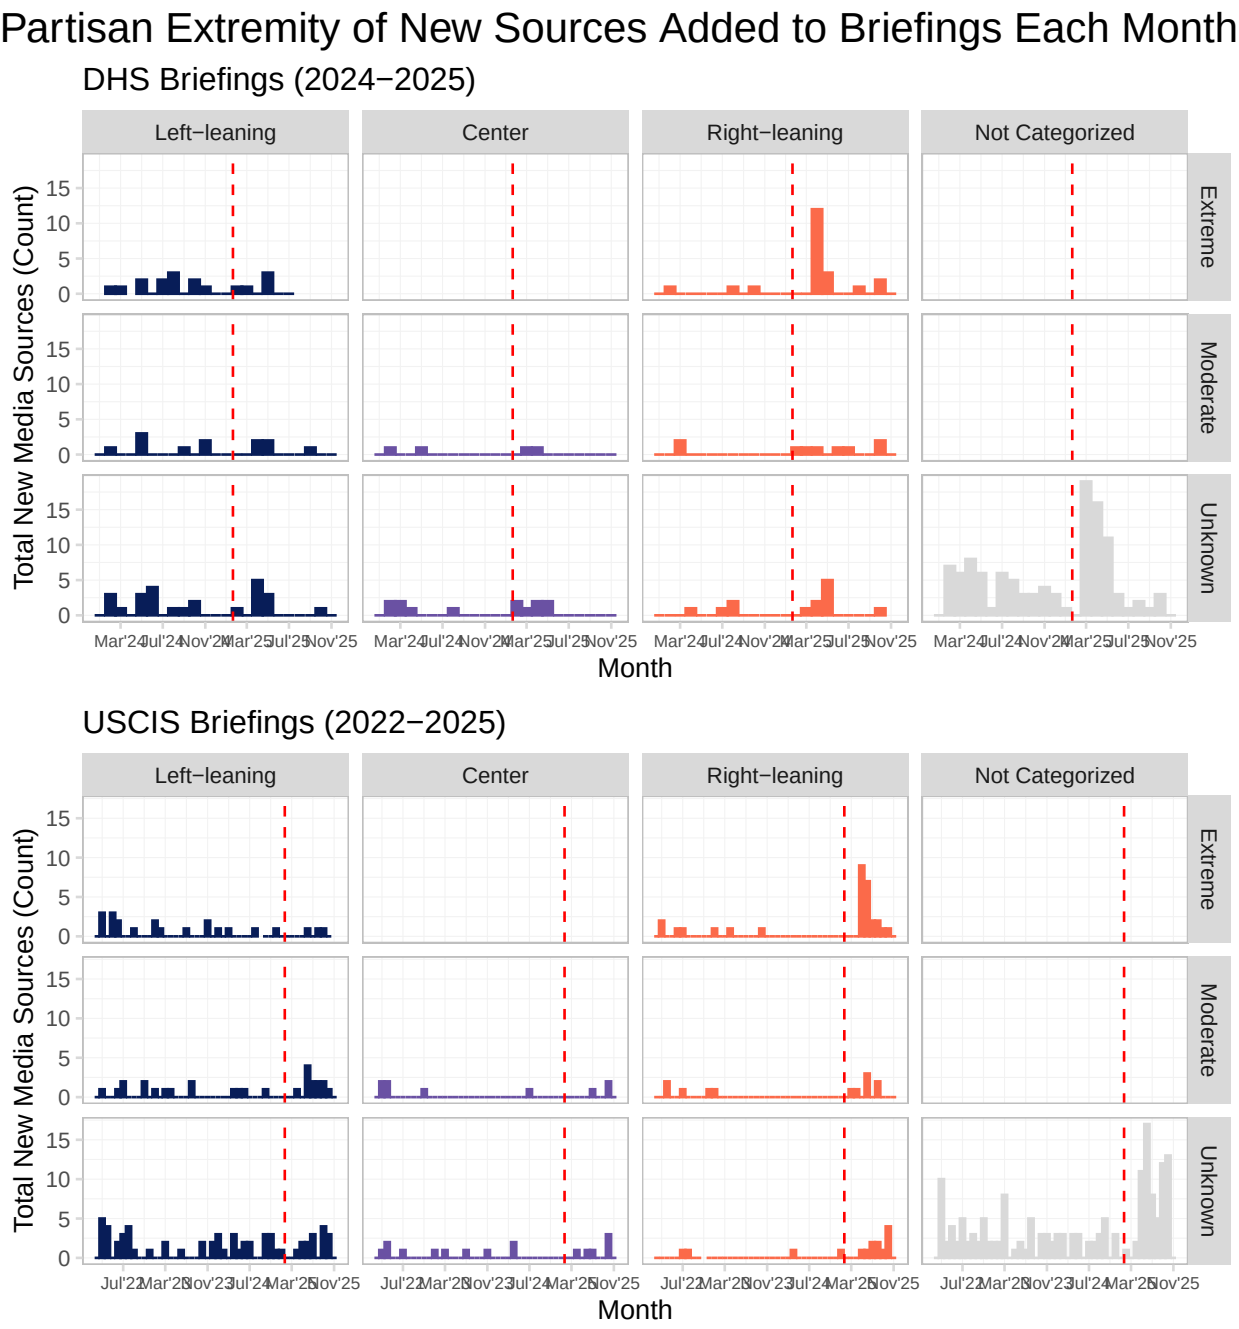

Figure A34: Number of new sources added to USCIS and DHS news briefings by month. Continuous MBFC scores are available for fewer news sources. Source extremity labeled as 'Unknown' if no continuous score is available.

A.9. Extension of Figure 6 Analysis - Using matched data to analyze selection over-time

In this section, I formally test whether a change in selection explains why the amount of right-leaning news increases dramatically around March/April 2025 in the DHS briefing. In theory, the matched data could also be used to test whether supply explains the pattern of conservative coverage in the briefings after March 2025. However, this comparison requires that the quality matched sample is stable over time and representative of the over-time changes in the content of the briefings. Below, I show that the matched sample does not perfectly capture the over-time trend that we observe in the briefings. The point estimates suggest that the increase in right-leaning news is due to preferential selection, but we should be cautious interpreting these results.

Over-time stability of Media Cloud data—Without knowing the true number of articles published by each outlet, assessing the quality of Media Cloud's data collection is difficult. However, there is some evidence that the quality of Media Cloud's data collection varies over time, which could affect comparison across administrations. To identify news outlets with varying quality, I downloaded the total number of articles collected by Media Cloud per day and domain, aggregated the data by week, and plotted the total articles over time (see Figure A35). I drop any domains with zero articles from 1/1/2024 to 10/26/2025.

Using the over-time stability of all articles collected by Media Cloud per week (see Figure A35), I grouped domains into three subsets: (1) "*All domains*" includes all domains that appear in both the DHS briefings and the Media Cloud output from 1/1/2024 to 10/26/2025. Media cloud output includes all agency name query output for DHS or the DHS subagencies. As with the other analyses in the paper, I drop local general interest news, government websites, and non-wire international sources. (2) "*Non-missing domains*" drops domains that are missing for large portions of the sample period. Most likely, the Media Cloud web scraper was broken during these periods. (3) "*Stable domains*" also drops domains that have substantial over-time instability. Over-time instability may indicate that the Media Cloud scraping pipeline was unstable, but it could also indicate that a news outlet has highly variable output.

Using Figure A35, I determined that the following domains were missing for large portions of the 2024-25 sample period and should be dropped from the over-time analyses. They are included in the "All domains" sample but excluded from the "Non-missing" and "Stable" samples.

- "bizpacreview.com" - missing after Sept 2024
- "business-standard.com" - only available from Sept to Oct 2024
- "caribbeannationalweekly.com" - missing from late 2024 through March 2025
- "justthenews.com" - missing after July/Aug 2025
- "knoxnews.com" - missing most weeks before March 2025
- "mrctv.org" - missing after Aug 2025
- "newsbusters.org" - missing after Aug 2025
- "nmpoliticalreport.com" - missing before Jan 2025
- "pilot.com" - missing before Sept 2024
- "politico.com" - missing after Feb 2024
- "scrippsnews.com" - mostly missing after May 2024
- "thedailybeast.com" - missing most weeks after Oct 2024
- "thestreet.com" - missing before March 2024
- "thewrap.com" - missing after Aug 2025
- "tpusa.com" - missing after Aug 2025
- "usnews.com" - missing most weeks in 2024
- "washingtonpost.com" - missing after March 2024
- "washingtontimes.com" - missing after July 2024

Using Figure A35, I determined that the following domains were unstable and should be dropped from the "Stable domains" sample. These domains are included in the "Non-missing" sample.

- "aol.com" - decline substantially before January 2025
- "apnews.com" - increases substantially around March/April 2025
- "bizjournals.com" - drops around May/June 2025
- "bloomberg.com" - increases substantially in Oct-Nov 2024
- "cnbc.com" - increases in Sept 2025
- "coindesk.com" - drops temporarily in July 2025
- "dailywire.com" - drops in Sept/Oct 2025
- "financialexpress.com" - drops briefly in July/Aug 2024
- "foxbusiness.com" - drops briefly several times in June/July/Aug 2024
- "freebeacon.com" - drops briefly in May 2024 and Dec 2024
- "nbcnews.com" - drops briefly in Sept/Oct 2024
- "npr.org" - increases around March 2024
- "nytimes.com" - drops briefly from Mar-April 2024

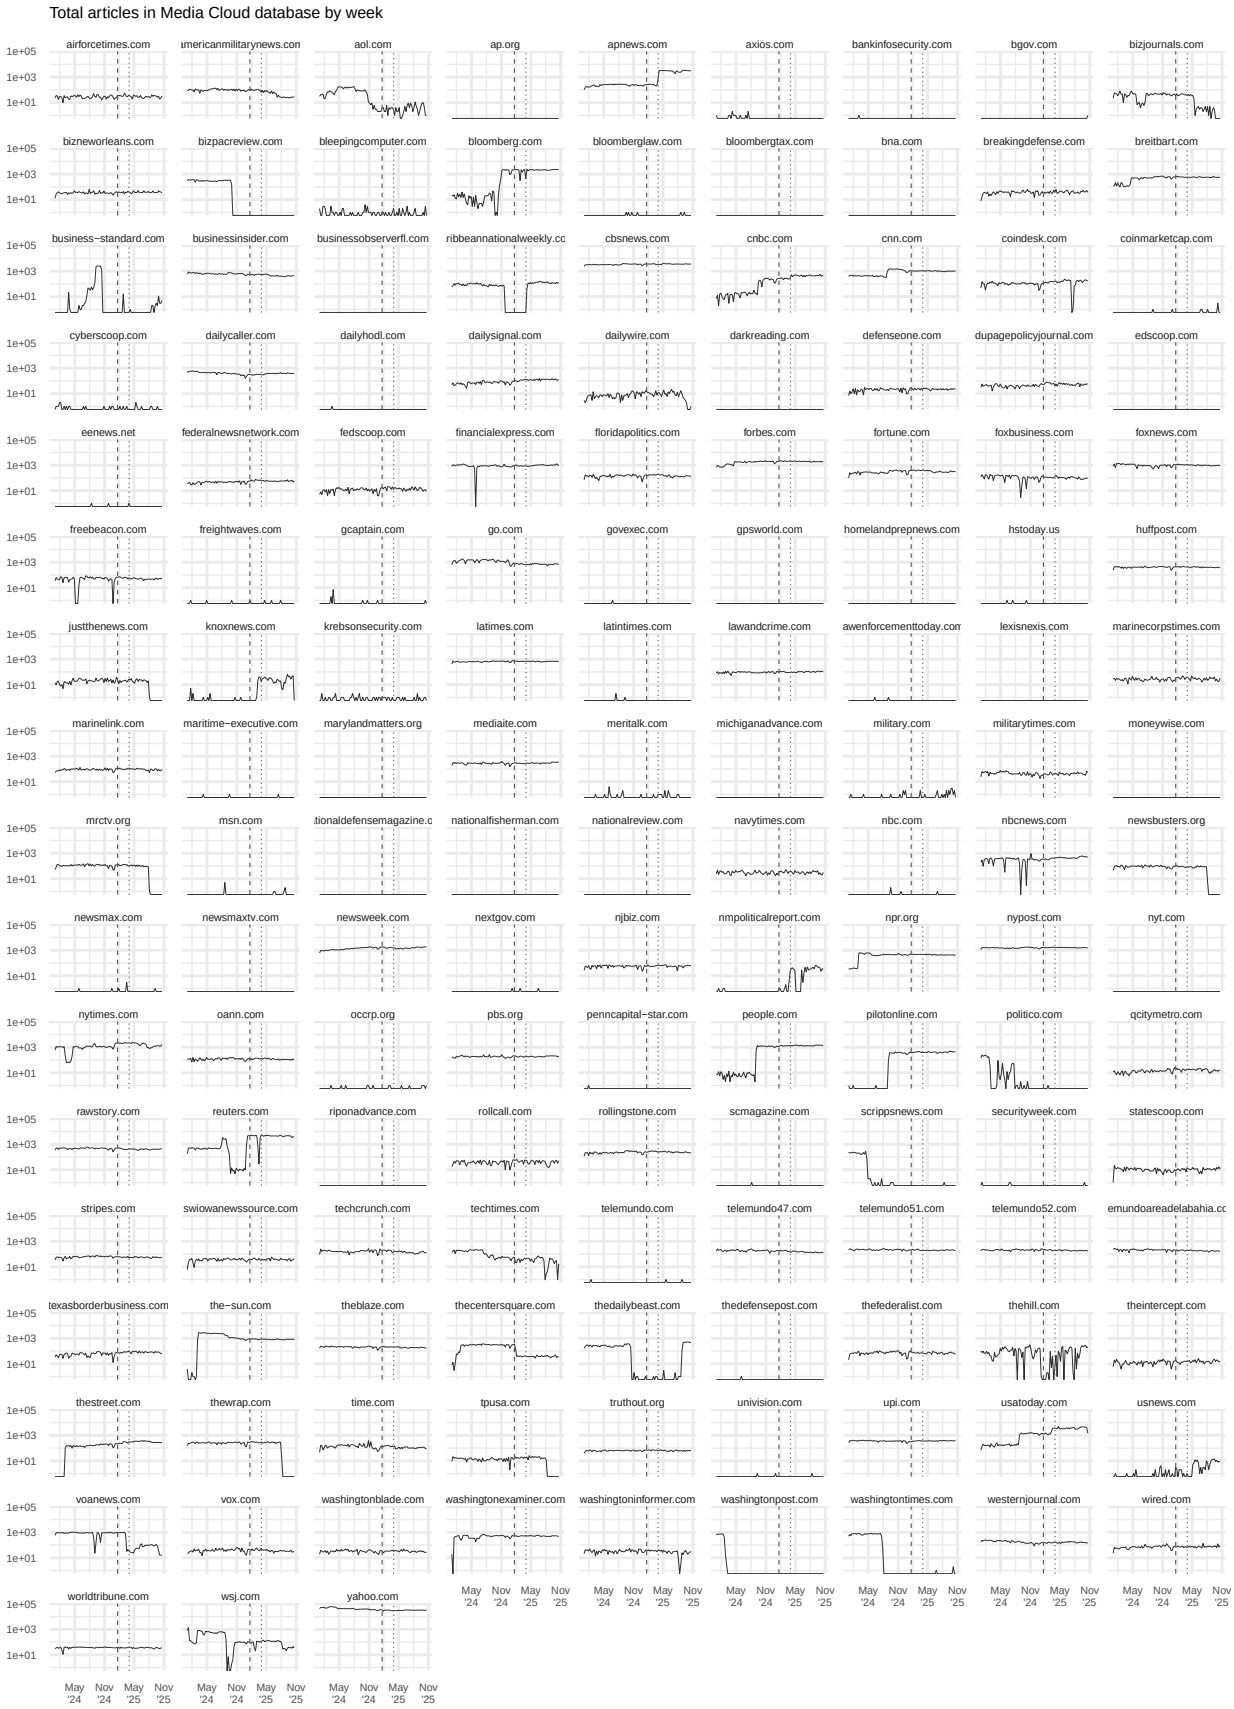

Figure A35: Total articles collected by Media Cloud by domain and week. Y axis is logged.

- “people.com” - increases substantially in Sept 2024
- “reuters.com” - drops substantially around Sept 2024, increases around Jan 2025, drops briefly in Mar 2025
- “techtimes.com” - drops gradually after May 2024, briefly drops sharply several times after July 2025
- “the-sun.com” - increases substantially around March 2024
- “thecentersquare.com” - increases gradually from January to March 2024, drops in January 2025
- “thehill.com” - total articles highly unstable
- “usatoday.com” - increases around Aug/Sept 2024
- “voanews.com” - drops briefly around Sept 2024, drops substancially around March 2025
- “washingtonexaminer.com” - increases substantially around Jan/Feb 2024
- “washingtoninformer.com” - drops briefly in Aug 2025
- “wsj.com” - Drops substancially in Sept 2024, recovers partially in Oct 2024

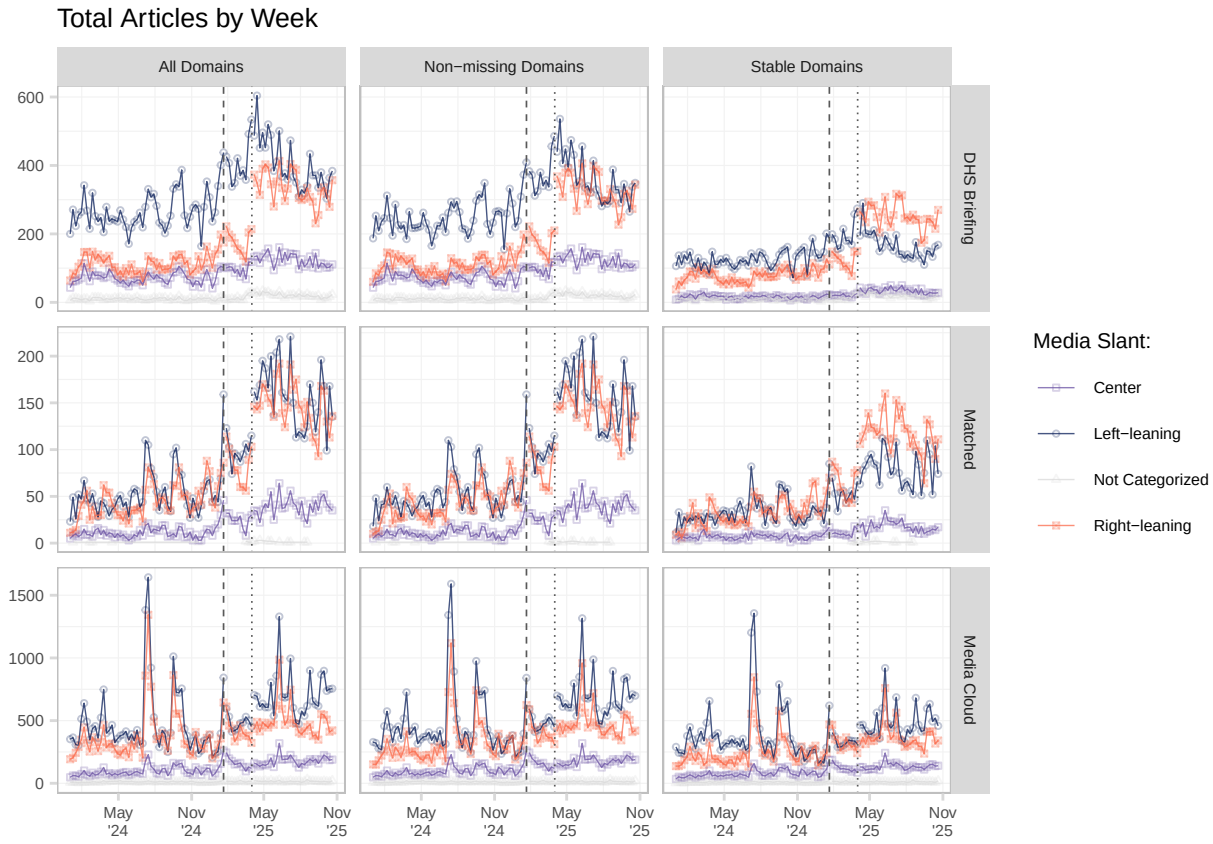

Figure A36: Total articles per week in DHS briefings, Media Cloud query output, and overlap between DHS briefings and Media Cloud. Dashed line at Trump’s 2025 inauguration. Dotted line at April 1, 2025.

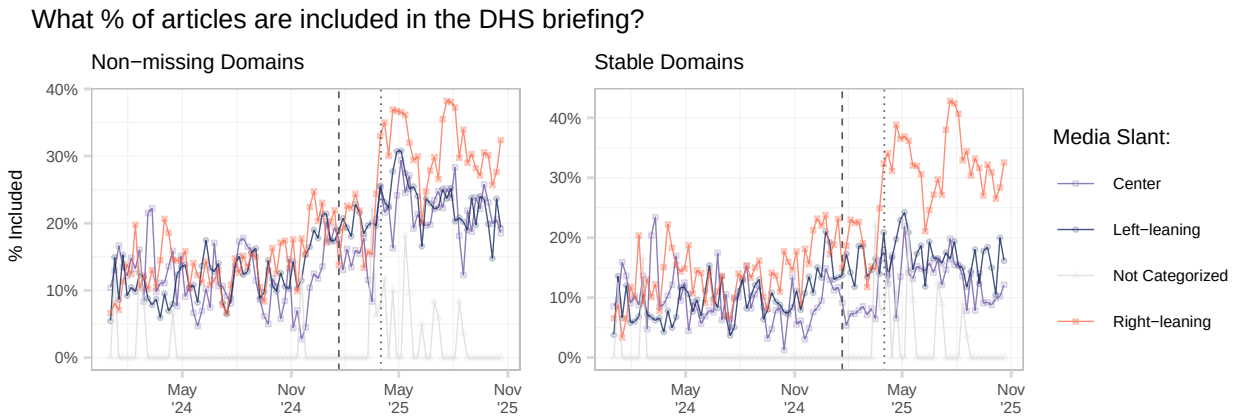

Figure A37: Over-time probability of coverage by partisan source category in the DHS news briefings. Calculated by week. Sample includes Media Cloud query output for DHS and all DHS subagencies. Outcome variable is binary indicator (1 if article included in news summary, 0 otherwise). Dashed line at Trump's 2025 inauguration. Dotted line at April 1, 2025.

Over-time representativeness—In Figure A36, I first plot the number of Left-leaning, Center, Right-leaning, and Not Categorized articles. Each row plots a different dataset: articles in the DHS briefings ("DHS Briefing"), Media Cloud DHS-query output ("Media Cloud"), or the articles found in to both the briefings and the Media Cloud output ("Matched"). Each column shows the results for different subsets of the data: "All Domains", "Non-missing Domains", and "Stable Domains."

Comparing the DHS briefing results to the Media Cloud and Matched results in Figure A36 reveals that DHS briefings contain relatively more Left-leaning news compared to Media Cloud and Matched datasets. This raises concerns about representativeness. Figure A36 also shows that the amount of Left-leaning news in the Media Cloud dataset appears to jump around April 1, 2025. Limiting the sample to stable domains reduces the size of this jump, but it raises concerns about it raises concerns about which outlets the stable panel leaves out.

Over-time selection rate—In Figure A37, I calculate the percent of articles in the Media Cloud sample that are included in the DHS briefing by week. For both the "Non-missing domains" and "Stable domains" subsets, right-leaning news sources become more likely to be selected/included in the briefings around March/April 2025.

Outlet-level estimates—For each outlet with at least 50 articles in the matched sample, I estimate a linear probability model: $\text{Included}_i = \alpha + \beta\,\text{Post}_i + \gamma\,t_i + \varepsilon_i$. t_i is the time since January 1, 2024, and Post_i indicates publication on or after April 1, 2025. The coefficient β is the change in inclusion probability at April 1, net of a linear trend. Standard errors are HC1 and clustered by publication week. Figure A38 reports $\widehat{\beta}$ with 95% confidence intervals for non-missing and stable outlets, colored by MBFC slant.

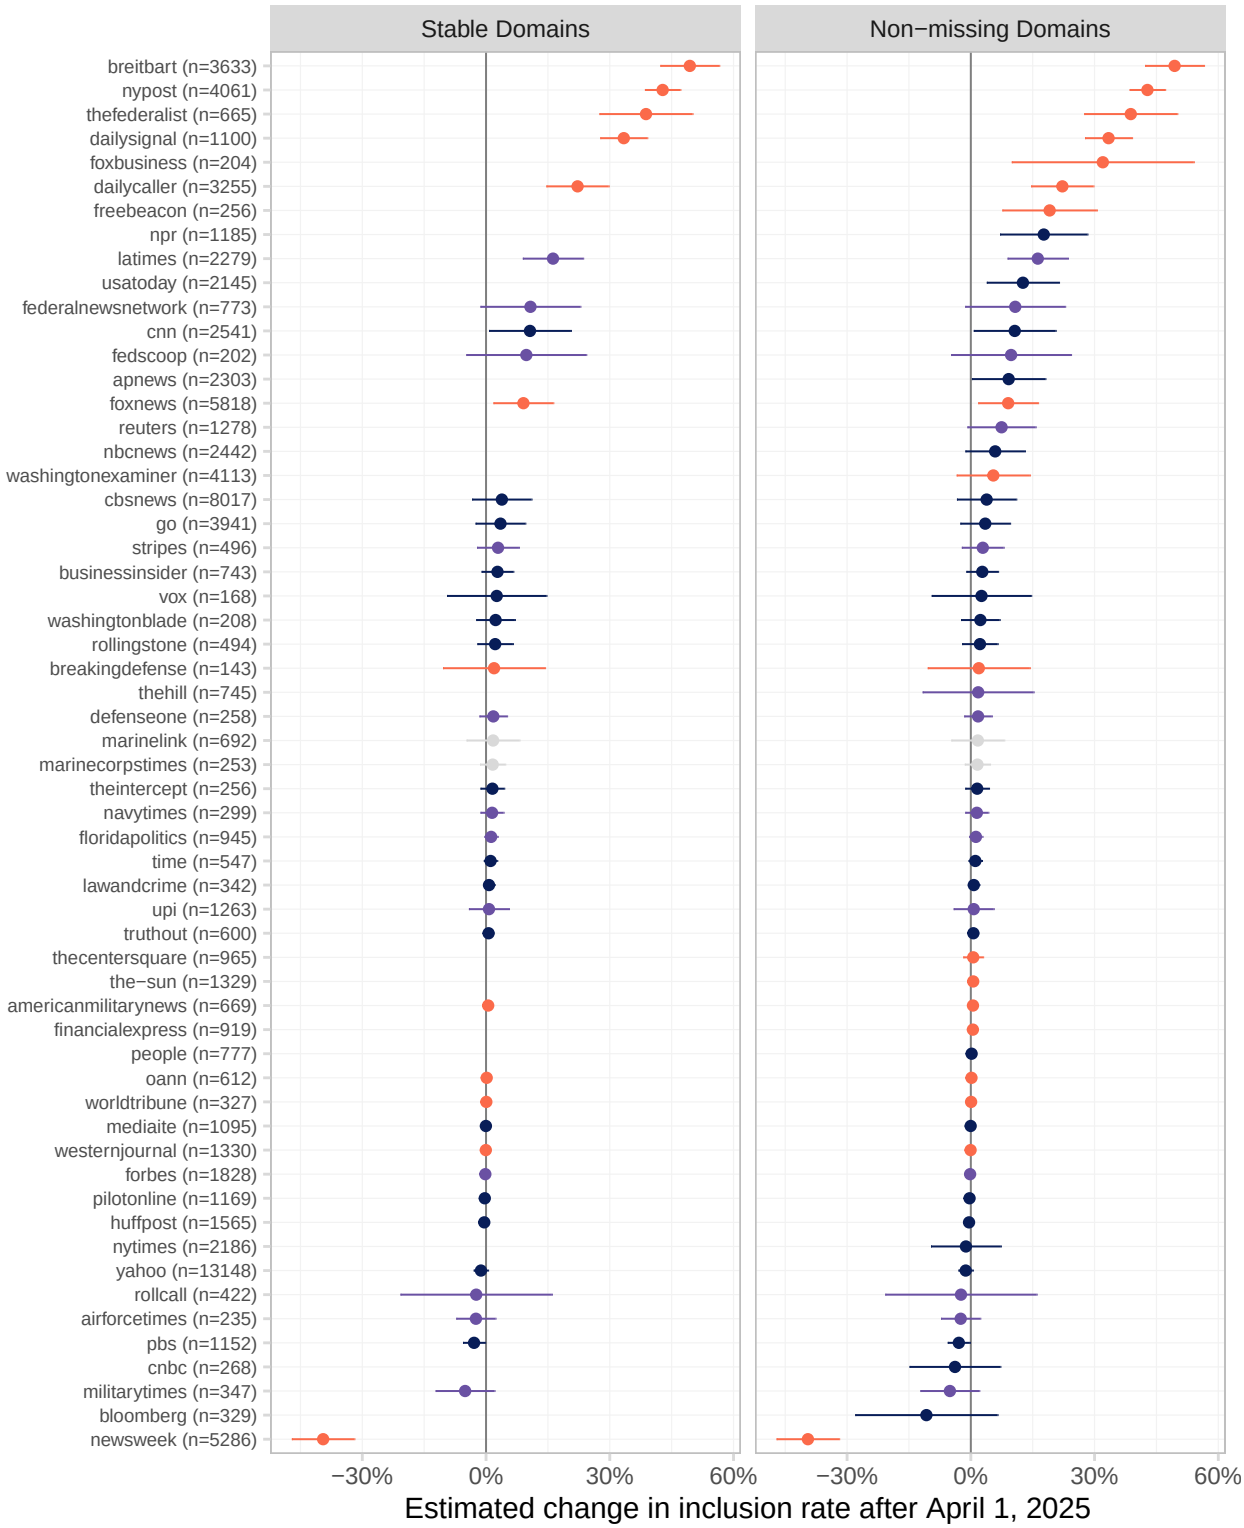

Figure A38: Change in probability that an article is included in the DHS briefing after April 1, 2025.

A.10. Extended Keyword Queries

A.10.1. Additional queries

I expanded the queries with two complementary sets of Boolean searches.

1. Component queries identify specific bureaus, offices, directorates, and programs using their formal names, common name variants, and—where a name is ambiguous—agency-specific contextual terms (e.g., DHS, FEMA, or USCIS).
2. Leader queries pair officials' names with either agency/component identifiers or their relevant position titles, creating alternative, more precise routes for capturing coverage of agency leadership while reducing false matches for common names.

A full list of queries can be found in the replication files. To establish a list of agency components, I used agency websites and organizational charts. To establish leader names, I relied on data from the Washington Post/Partnership for Public Service and FedScope. For the USCIS, I obtained a list of leaders from its website.

Using FedScope, I identified 89 Executive Schedule records covering Interior from 2015 to 2019, VA from 2020 to 2021, and DHS from 2022 to 2024. Depending on the year, FedScope labels Executive Schedule positions as either EX' ' or EXEC.' ' I treat these labels as equivalent. The grade variable ranges from 01 to 05 and corresponds to Executive Schedule Levels I through V. The resulting records primarily capture presidentially-appointed and Senate-confirmed officials, including department secretaries, directors, and administrators.

A.10.2. Extended query hit rates in scraped sample

The following tables replicate the tables in section A.6.2 using the extended queries:

- Table A18 reports the share of successfully scraped articles whose recovered text contains one of the extended keywords. Hit rates are reported by agency, briefing, and keyword type
- Table A19 shows how hit rates vary across sections of the DHS briefing. The columns represent the keyword queries for each DHS subagency. Thus, the CG column is the hit rate for "Coast Guard," the DHS column is the hit rate for "Homeland Security," etc.
- Table A20 shows how hit rates vary across sections of the USCIS briefing. The columns represent the keyword queries for each DHS subagency.
- Table A21 compares the html-full-text hit rates to the summary text hit rates.
- Table A22 shows the hit rate for each DOI agency name in each section of the DOI summary.

Table A18: Extended-keyword hit rates in high-quality full-text extractions.

Document	Agency / briefing	Scraped URLs	Percent of URLs with a hit			
			Any keyword	Agency name	Leader	Component
DHS section	Coast Guard	191	93%	93%	5%	15%
DHS section	FEMA	601	26%	24%	3%	4%

A.10.3. Comparing articles with and without extended queries

The following tables replicate the tables in section A.6.3 using the extended queries:

- Figure A39 reproduces the right-leaning subplot of Figure 1 using all of the successfully scraped articles, the scraped articles with query hits, and the scraped articles without query hits.
- Figure A40 reproduces the right-leaning subplot of Figure 1 using all of the briefing articles, the briefing articles with summaries that contain query hits, and the articles without summary hits.

Table A22: Extended-query hit rates by DOI briefing section. Entries are percentages of effective summaries.

ABB	Section	N	Percent of summaries with a hit							
			Any agency	BIA	BLM	BOR	DOI	FWS	GS	NPS
BLM	Bureau of Land Management	74	35%	0%	24%	0%	7%	3%	0%	4%
FWS	Fish and Wildlife Service	131	38%	0%	0%	0%	3%	33%	0%	4%
GS	US Geological Survey	19	26%	0%	0%	0%	0%	0%	26%	0%
NPS	National Park Service	169	64%	0%	0%	0%	0%	0%	0%	64%
-	BIG PICTURE	2	0%	0%	0%	0%	0%	0%	0%	0%
-	DOI IN THE NEWS	316	28%	1%	5%	0%	19%	4%	0%	6%
-	EDITORIAL WRAP-UP	217	1%	0%	0%	0%	0%	0%	0%	0%
-	EMPOWERING NATIVE AMERICAN COMMUNITIES	99	42%	16%	0%	2%	31%	0%	0%	0%
-	OFFICE OF INSULAR AFFAIRS	1	0%	0%	0%	0%	0%	0%	0%	0%
-	Offshore Energy Development	94	17%	0%	2%	0%	15%	0%	1%	0%
-	Onshore Energy Development	83	30%	0%	6%	0%	18%	1%	1%	7%
-	Renewable Energy	34	12%	0%	0%	0%	12%	3%	0%	0%
-	TACKLING AMERICA'S WATER CHALLENGES	81	12%	0%	0%	12%	1%	0%	0%	0%
-	TOP NATIONAL NEWS	1,446	0%	0%	0%	0%	0%	0%	0%	0%
-	**Total**	**2,766**	**14%**	**1%**	**2%**	**0%**	**5%**	**2%**	**0%**	**5%**
-	**Total (less top national news and editorial wrap-up)**	**1,103**	**34%**	**2%**	**4%**	**1%**	**12%**	**6%**	**1%**	**13%**

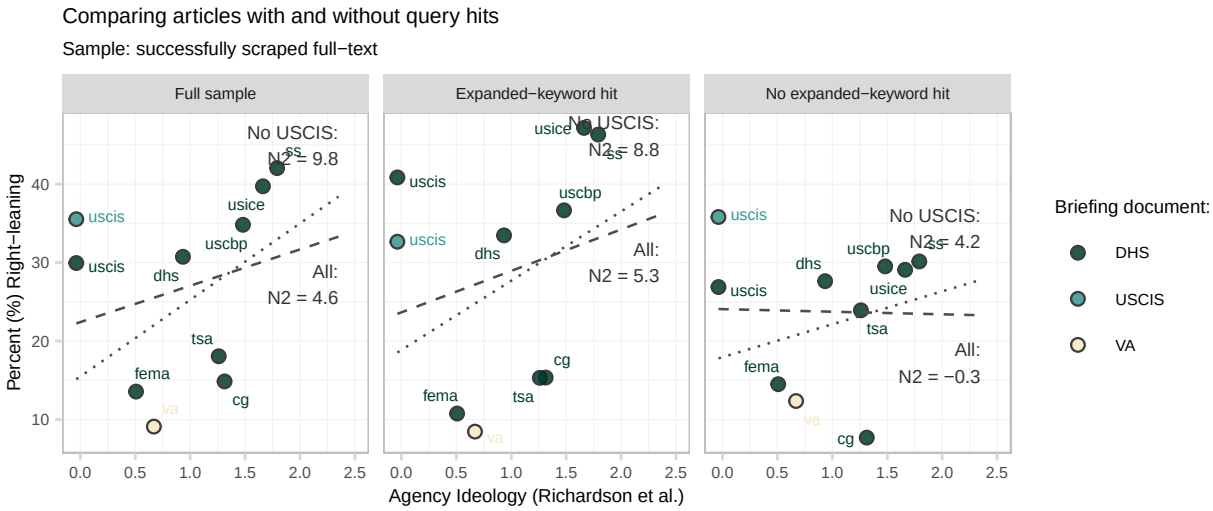

Figure A39: Representativeness of articles that contain agency extended query hits (scraped full text sample). Relationship between agency ideology and right-leaning media slant for whole sample, articles that contain agency names, and articles without agency names. Sample is restricted to scraped articles with high-quality full text.

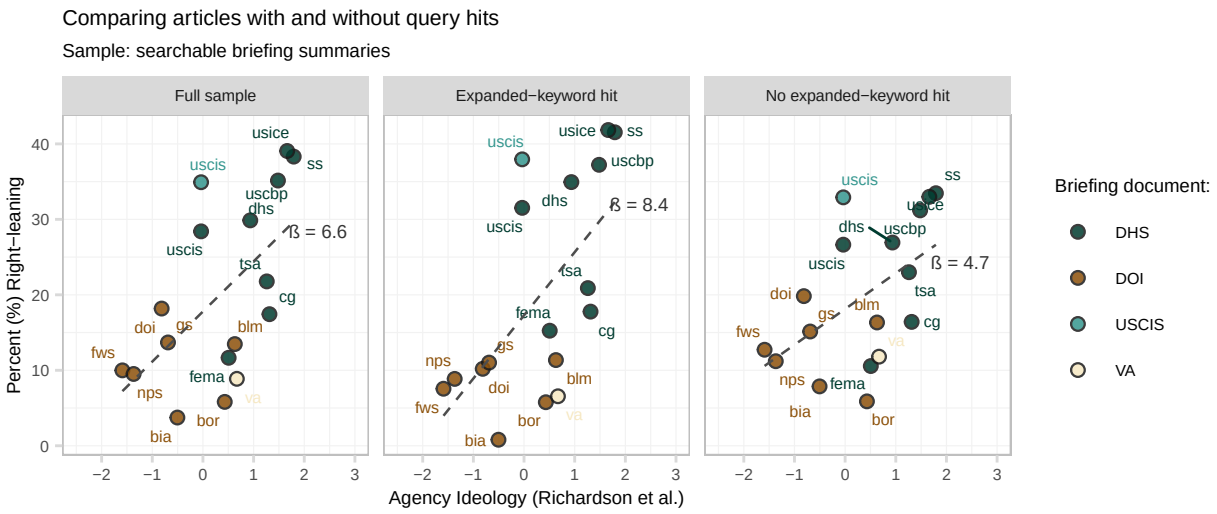

Figure A40: Representativeness of articles that contain agency extended query hits (estimated from summaries). Relationship between agency ideology and right-leaning media slant for whole sample, articles with summaries that contain agency names, and articles with summaries that do not contain agency names. Dropped government sources, local general interest sources, and non-wire international sources. Dropped articles with no summary data.

A.10.4. Replication of Figure A1 (DOI Representativeness) with extended queries

Figure A41 replicates Figure A1 in section A.1.1. using the extended keywords to construct the supply of potentially-relevant DOI news.

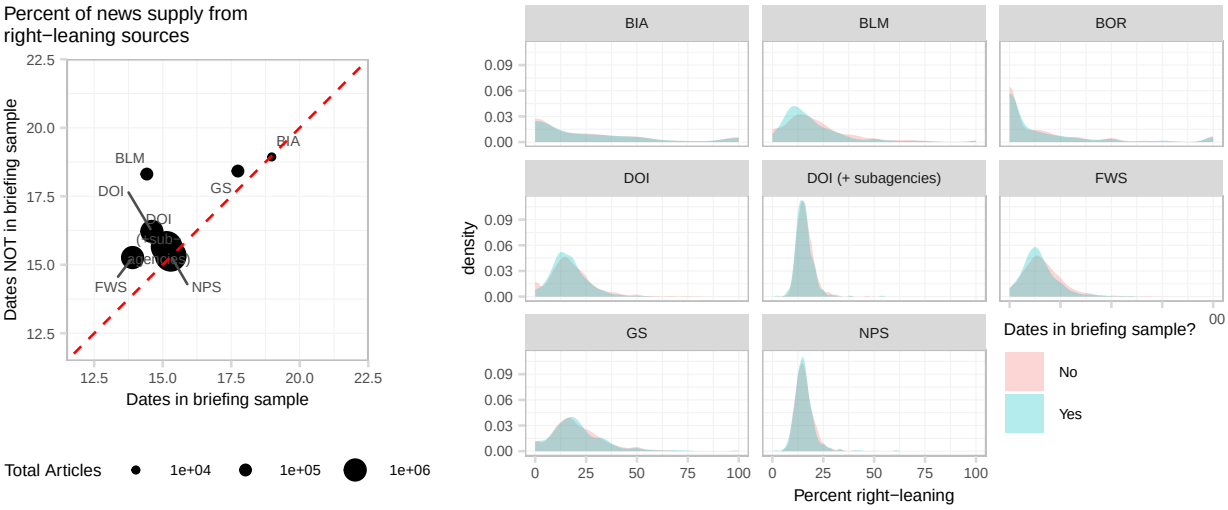

Figure A41: Comparison of DOI news supply on dates represented in the briefing sample and on other dates during the same period. Data from Media Cloud extended queries. Density plots show distribution of data aggregated to the level of publication date for the density plots.

A.10.5. Replication of Figure 3 with extended queries

Figure A42 replicates Figure 3 with the extended queries.

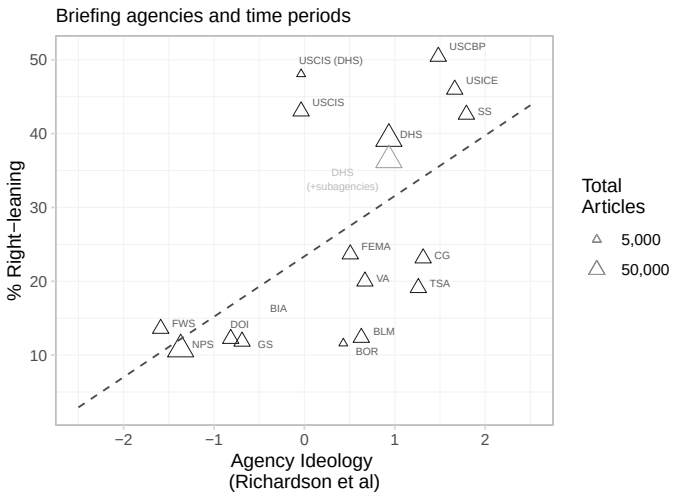

Figure A42: Supply of partisan news that contains extended queries. Based on extended Media Cloud queries during time periods covered by briefings. The best fit line excludes 'DHS (+subagencies)'.

A.10.6. Replication of Figure 4 with extended queries

The following plots replicate Figure 4 in the paper and the robustness checks in A.7 using the extended queries:

- Figure A45 replicates Figure A25 in section A.7.

- Figure A43 replicates Figure A23 in section A.7.
- Figure A44 replicates Figure A24 in section A.7.
- Figure A46 replicates Figure 4 with the extended queries.
- Figure A47 replicates Figure A26 in section A.7 using the extended keywords to construct the supply of potentially-relevant news.

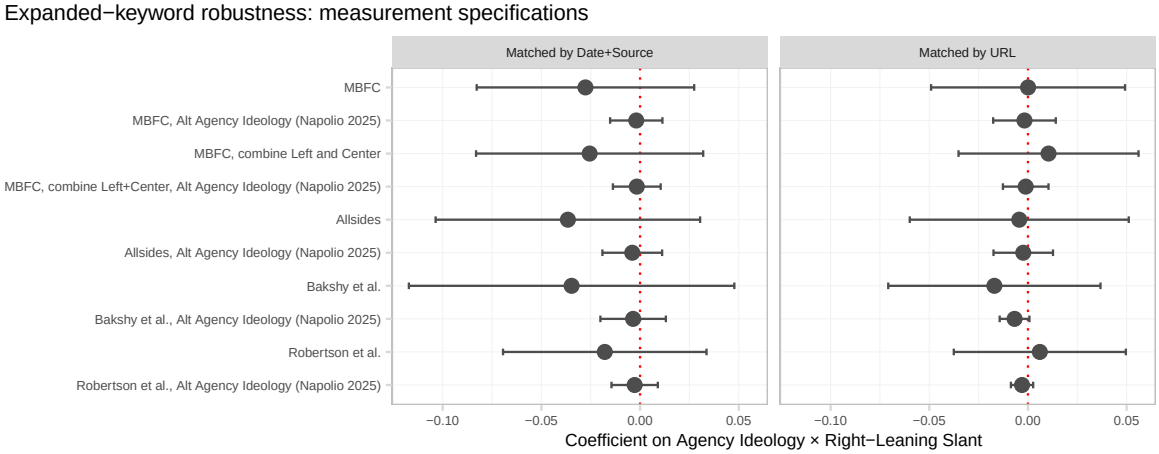

Figure A43: Robustness of interaction effect in Figure 4 to different measures with extended query sample.

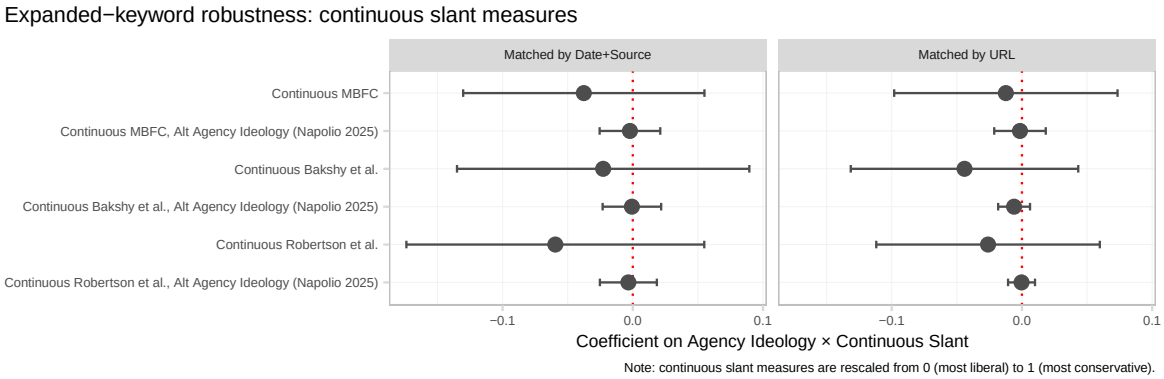

Figure A44: Robustness of interaction effect in Figure 4 to continuous slant measures with extended query sample.

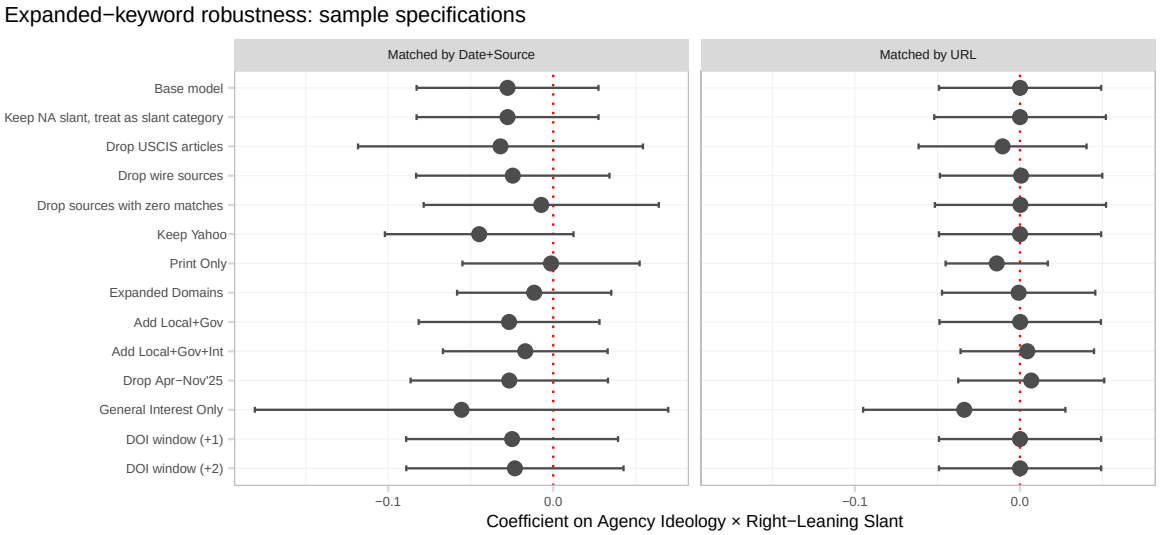

Figure A45: Robustness of interaction effect in Figure 4 to different samples with extended query sample.

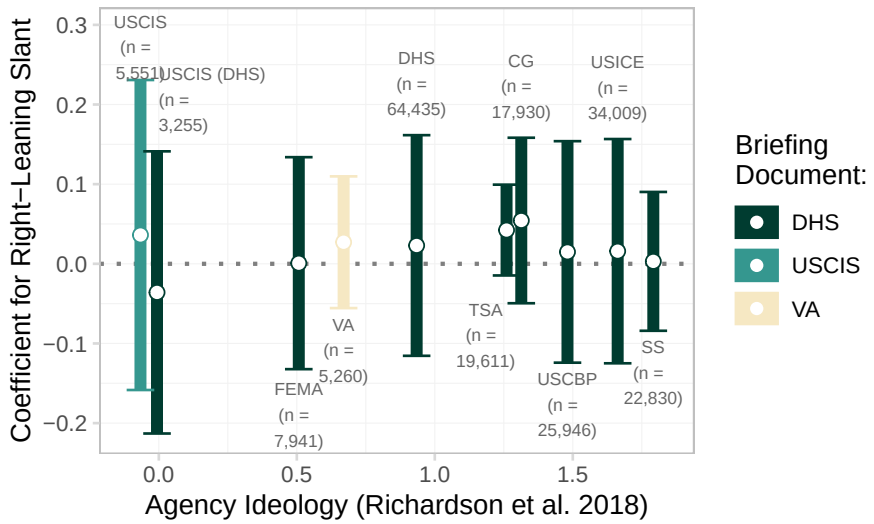

Figure A46: Alternate specifications for Figure 4 - Extended queries, matched by URL.

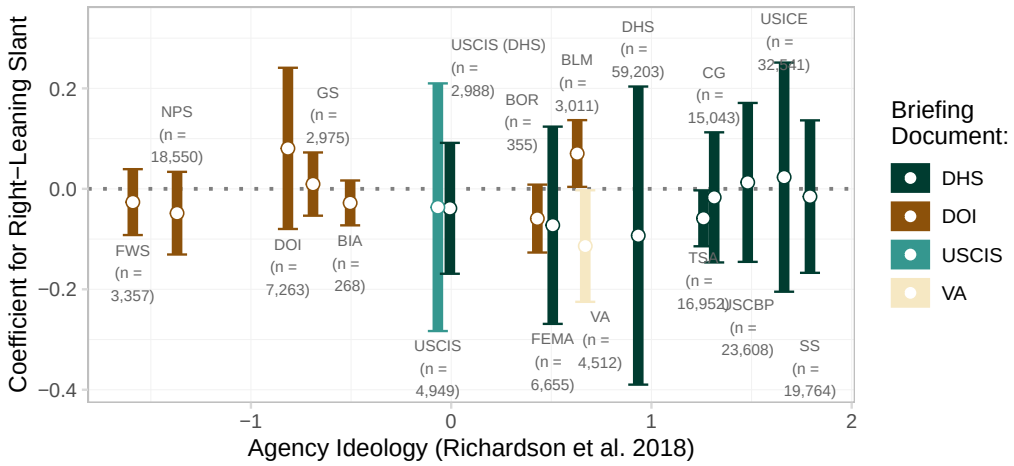

Figure A47: Alternate specifications for Figure 4 - Extended queries, matched by Source+Date.
